Chapter 1

Introduction

Hardware Software Interface (HSI) is a scalable framework enabling embedded SW tool integration with Vivado. It enables third-party OS vendors and software providers to distribute their software for Xilinx FPGA Platforms. HSI consumes hardware design (.hdf) files and the software repository (Drivers, OS, board support packages (BSPs), Libs, Apps, and DTG). It provides a rich set of Tcl APIs to access hardware information and to generate BSPs, Device Tree, and template applications.

Figure 1: Design Flow Using HSI
Chapter 2

Hardware Handoff

This chapter describes the Vivado hardware handoff flow for the pre-synthesis and post-bitstream designs. The figure below shows the IP integrator Zynq ZC702 example design.

Figure 2: Example Zynq Design and Bus Functional Simulation

CAUTION!: Vivado hardware handoff flow supports only single Block Diagram and independent multi Block Diagram designs. It does not support RTL, Reference Block Diagram, and dependent multi-Block Diagram designs.
Pre-Synthesis Hardware Handoff

GUI Project Flow

Do the following to perform pre-synthesis hardware handoff in the Vivado interface.

1. Generate the block design. To do this:
   a. In the Flow Navigator under IP Integrator, click Generate Block Design. The Generate Output Products dialog box opens.
   b. Click Generate to generate the block design.

2. Export the hardware design. To do this:
   a. Select File > Export > Export Hardware. The Export Hardware dialog box opens.
b. Leave the **Include bitstream** check box unchecked.

c. Click **OK** to export the hardware design.

### Tcl Projectless Flow

Use the following Tcl commands to perform pre-synthesis hardware handoff using Tcl commands outside of the Vivado project.

1. `create_project -in_memory -part xc7z020clg484-1`
2. `set_property board_part xilinx.com:zc702:part0:1.0 [current_project]`
3. `read_bd base_zynq_design.bd`
4. `read_vhd base_zynq_design_wrapper.vhd`
5. `generate_target all [get_files base_zynq_design.bd]`
6. `write_hwdef -file base_zynq_design_wrapper.hdf`

### Post-Bitstream Hardware Handoff

### GUI Project Flow

Do the following to perform post-bitstream hardware handoff in the Vivado interface.

1. Generate the block design. To do this:

   a. In the **Flow Navigator** under **Program and Debug**, click **Generate Bitstream**. The following dialog box opens.
b. Click Yes to launch synthesis and implementation. When synthesis and implementation complete, the Generate Bitstream process automatically runs.

2. Export the hardware design. To do this:
   
a. Select File > Export > Export Hardware. The Export Hardware dialog box opens.
   
   ![Export Hardware dialog box]

   b. Check the Include bitstream check box.
   
c. Click OK to export the hardware design and include the bitstream.

**Tcl Projectless Flow**

Use the following Tcl commands to perform post-bitstream hardware handoff using Tcl commands outside of the Vivado project.

1. `create_project -in_memory -part xc7z020clg484-1`
2. `set_property board_part xilinx.com:zc702:part0:1.0[current_project]`
3. `read_bd base_zynq_design.bd`
4. `read_vhd base_zynq_design_wrapper.vhd`
5. `generate_target all [get_files base_zynq_design.bd]`
6. `synth_design -top base_zynq_design_wrapper`
7. `opt_design`
8. `place_design`
9. `write_hwdef -file base_zynq_design_wrapper.hwdef`
10. route_design
11. write_bitstream base_zynq_design_wrapper.bit
12. write_sysdef -hwdef base_zynq_design_wrapper.hwdef -bitfile base_zynq_design_wrapper.bit -file base_zynq_design_wrapper.hdf
Chapter 3

Tcl Capabilities Overview

The Tool Command Language (Tcl) is the scripting language integrated in the Hardware Software Interface (HSI) environment.

Tcl lets you perform interactive queries to design tools and execute automated scripts. Tcl offers the ability to “ask” questions interactively of design databases, particularly around tool and design settings and state. Examples are:

- Querying IP, Driver, BSP, and Driver configuration
- Querying interrupt and other connectivity information

The following sections describe some of the basic capabilities of Tcl with HSI.

Note: This manual is a reference to the specific capabilities of the HSI Tcl shell, and provides reference to additional Tcl programming resources. It is not a comprehensive reference for the Tcl language.

First Class Tcl Object Types and Relationships

Hardware

- HardwareDb: Represents hardware design loaded in memory. SDK, PetaLinux, and third-party tools can have multiple HardwareDb objects.
- Port: A special type of pin on the top-level module or entity. Ports are normally attached to I/O pads and connect externally to the FPGA device.
- InterfacePort: A special type of bus-interface on the top level module or entity. Interface Ports are normally attached to I/O pads and connect externally to the FPGA device.
- Net: A wire or list of wires that eventually can be physically connected directly together. Nets can be hierarchical or flat, but always sort a list of pins together.
- InterfaceNet: A list of wires that eventually can be physically connected directly together. Interface nets can be hierarchical or flat, but always sort a list of interface pins together.
• **Pin**: A point of logical connectivity on a cell. A pin allows the internals of a cell to be abstracted away and simplified for easier use on cell. Examples of pins include clock, data, reset, and output pins of a flop.

• **InterfacePin**: A point of logical connectivity on a cell. It allows the internals of a cell to be abstracted away and simplified for easier use on cell. Examples of interface pins include the M_AXI_DP interface of MicroBlaze processors, and the S_AXI interface of gpio.

• **Cell**: The instantiation of IP in the hardware design. Examples of cells include instantiation of microblaze, gpio, and axi_dma, as well as hierarchical instances which are wrappers for other groups of cells.

• **MemoryRange**: Represents the memory range associated with the peripherals in the memory map of the processor.

• **SupportingDesignFile**: Represents files associated with the hardware design. For example, .bit or .mmi.

**Hardware Object Relationships**

![Hardware Object Relationships Diagram](image)

**Software**

• **SoftwareDb**: Represents one software design or microprocessor software specification (MSS). SDK, PetaLinux, and other third-party tools can have multiple SoftwareDb objects.

• **SwCore**: Represents driver/library/OS present in the software repositories. For example: cpu, gpio, standalone, xilffs.

• **SwProcessor**: The driver mapped to the processor instance in the hardware design. For example: cpu driver mapped for MicroBlaze processor cell.
• **SwDriver**: The driver mapped to the peripheral instance in the hardware design. For example: gpio driver mapped for axi_gpio cell.

• **SwLibrary**: The library added in the software design. For example: xilflash, xilffs.

• **SwOS**: The OS in the software design. For example: standalone, xilkernel.

• **SwInterface**: The interface of the library/driver. It describes the interface functions and header files used by the library/driver. For example: stdin, stdout of uart driver.

• **SwArray**: The array defined in driver/library/os. It contains any number of PARAMs and PROPERTYs which describe the size and description of the array and default values of elements in the array. It represents software array of the driver/library/os. For example: mem_table, shm_table of xilkernel bsp.

• **SwDTNode**: Represents node in Device Tree (DTS) file.

• **SwParam**: Represents parameters of node.

- hsi::open_sw_design
- hsi::set_repo_path

Tools

- common::load_features
This chapter demonstrates how to load a .hdf file, access the hardware information, and generate BSPs, applications, and the Device Tree.

## Accessing Hardware Design Data

### # Opening the hardware design

```tcl
hsi::open_hw_design base_zynq_design_wrapper.hdf
base_zynq_design_imp
```

### # List loaded hardware designs

```tcl
hsi::get_hw_designs
base_zynq_design_imp
```

### # Switch to current hardware design

```tcl
hsi::current_hw_design
base_zynq_design_imp
```

### # Report properties of the current hardware design

```tcl
common::report_property [hsi::current_hw_design]
```

Chapter 5

Input and Output Files

Input Files

HDF

Hardware Design File (.hdf) is a Xilinx proprietary file format and only Xilinx software tools understand it. Third-party software tools can communicate to the HSI Tcl interface to extract data from the .hdf file.

*Note:* Xilinx does not recommend manually editing the HDF file or altering its contents.

HDF is a container and contains:

- One or more .hwh files
  - Vivado tool version, part, and board tag information
  - IP - instance, name, VLNV, and parameters
  - Memory Map information of the processors
  - Internal Connectivity information (including interrupts, clocks, etc.) and external ports information
- BMM/MMI and BIT files
- User and HLS driver files
- Other meta-data files

Software Repository

Default Repositories

By default, the tool scans the following repositories for software components:

- `<install>/data/embeddedsw/lib/XilinxProcessorIPLib`
- `<install>/data/embeddedsw/lib`
• \texttt{<install>/data/embeddedsw/ThirdParty}

The following figure shows the repository directory structure.

\textit{Figure 5: Example Directory Structure}

\begin{center}
\includegraphics[width=0.8\textwidth]{example_directory_structure.png}
\end{center}

\textbf{GIT Repositories}

The Device Tree repository can be cloned from Xilinx GIT. Use the \texttt{set_repo_path} Tcl command to specify the cloned GIT repository.

\textbf{User Repositories}

You can create drivers, BSPs, and Apps in an example directory structure format, as illustrated in the figure above. Use the \texttt{set_repo_path} Tcl command to specify the user repository.

\textbf{Search Priority Mechanism}

The tool uses a search priority mechanism to locate drivers and libraries, as follows:

1. Search the repositories under the library path directory specified using the \texttt{set_repo_path} Tcl command.
2. Search the default repositories described above.

\section*{Output Files}

The tool generates directories, files, and the software design file (MSS) in the \texttt{<your_project>} directory. For every processor instance in the MSS file, the tool generates a directory with the name of the processor instance. Within each processor instance directory the tool generates the following directories and files.

• The include Directory:
The include directory contains C header files needed by drivers. The include file \texttt{xparameters.h} is also created using the tool in this directory. This file defines base addresses of the peripherals in the system, #defines needed by drivers, OSs, libraries, and user programs, as well as function prototypes.

- The Microprocessor Driver Definition (MDD) file for each driver specifies the definitions that must be customized for each peripheral that uses the driver. See Microprocessor Driver Definition (MDD) Overview.

- The Microprocessor Library Definition (MLD) file for each OS and library specifies the definitions that you must customize. See Microprocessor Library Definition (MLD) Overview.

- The lib Directory:

  The \texttt{lib} directory contains \texttt{libc.a}, \texttt{libm.a}, and \texttt{libxil.a} libraries. The \texttt{libxil} library contains driver functions that the particular processor can access. For more information about the libraries, refer to the introductory section of the OS and Libraries Document Collection (UG643).

- The libsrc Directory:

  The \texttt{libsrc} directory contains intermediate files and make files needed to compile the OSs, libraries, and drivers. The directory contains peripheral-specific driver files, BSP files for the OS, and library files that are copied from install, as well as your driver, OS, and library directories. Refer to Drivers, OS Block, and Libraries for more information.

- The code Directory:

  The code directory is a repository for tool executables. The tool creates an \texttt{xmdstub.elf} file (for the MicroBlaze™ processor on-board debug) in this directory.

\textit{Note}: The tool removes these directories every time you run the it. You must put your sources, executables, and any other files in an area that you create.

---

**Generating Libraries and Drivers**

This section provides an overview of generating libraries and drivers. The hardware specification file and the MSS files define a system. For each processor in the system, the tool finds the list of addressable peripherals. For each processor, a unique list of drivers and libraries are built. The tool does the following for each processor:

- Builds the directory structure, as defined in Output Files.
- Copies the necessary source files for the drivers, OSs, and libraries into the processor instance specific area: \texttt{OUTPUT_DIR/processor_instance_name/libsrc}.  

\text{UG1138 (v2019.1) May 22, 2019}
• Calls the Design Rule Check (DRC) procedure, which is defined as an option in the MDD or MLD file, for each of the drivers, OSs, and libraries visible to the processor.

• Calls the `generate` Tcl procedure (if defined in the Tcl file associated with an MDD or MLD file) for each of the drivers, OSs, and libraries visible to the processor. This generates the necessary configuration files for each of the drivers, OSs, and libraries in the include directory of the processor.

• Calls the `post_generate` Tcl procedure (if defined in the Tcl file associated with an MDD or MLD file) for each of the drivers, OSs, and libraries visible to the processor.

• Runs `make` (with targets include and libs) for the OSs, drivers, and libraries specific to the processor. On the Linux platform, the `gmake` utility is used, while on NT platforms, `make` is used for compilation.

• Calls the `execs_generate` Tcl procedure (if defined in the Tcl file associated with an MDD or MLD file) for each of the drivers, OSs, and libraries visible to the processor.

### MDD, MLD, and Tcl

A driver or library has two associated data files:

• **Data Definition File (MDD or MLD file):** This file defines the configurable parameters for the driver, OS, or library.

• **Data Generation File (Tcl):** This file uses the parameters configured in the MSS file for a driver, OS, or library to generate data. Data generated includes but is not limited to generation of header files, C files, running DRCs for the driver, OS, or library, and generating executables.

The Tcl file includes procedures that tool calls at various stages of its execution. Various procedures in a Tcl file include:

- **DRC:** The name of DRC given in the MDD or MLD file.

- **generate:** A tool-defined procedure that is called after files are copied.

- **post_generate:** A tool-defined procedure that is called after generate has been called on all drivers, OSs, and libraries.

- **execs_generate:** A tool-defined procedure that is called after the BSPs, libraries, and drivers have been generated.

*Note:* The data generation (Tcl) file is not necessary for a driver, OS, or library.

For more information about the Tcl procedures and MDD/MLD related parameters, refer to Microprocessor Driver Definition (MDD) Overview and Microprocessor Library Definition (MLD) Overview.
**MSS Parameters**

For a complete description of the MSS format and all the parameters that MSS supports, refer to [MSS Overview](#).

**Drivers**

Most peripherals require software drivers. The peripherals are shipped with associated drivers, libraries and BSPs. Refer to the *Device Driver Programmer Guide* for more information on driver functions. This guide is located in your SDK installation, in `<install_directory>/SDK/<version>/data/embeddedsw/doc/xilinx_drivers_guide.pdf`.

The MSS file includes a driver block for each peripheral instance. The block contains a reference to the driver by name (DRIVER_NAME parameter) and the driver version (DRIVER_VER). There is no default value for these parameters.

A driver has an associated MDD file and a Tcl file.

- The driver MDD file is the data definition file and specifies all configurable parameters for the drivers.
- Each MDD file has a corresponding Tcl file which generates data that includes generation of header files, generation of C files, running DRCs for the driver, and generating executables.

You can write your own drivers. These drivers must be in a specific directory under `/drivers`, as shown in the figure in *Software Repository*.

- The DRIVER_NAME attribute allows you to specify any name for your drivers, which is also the name of the driver directory.
- The source files and make file for the driver must be in the `/src` subdirectory under the `/` directory.
- The make file must have the targets `/include` and `/libs`.
- Each driver must also contain an MDD file and a Tcl file in the `/data` subdirectory.

Open the existing driver files to get an understanding of the required structure.

Refer to [Microprocessor Driver Definition (MDD) Overview](#) for details on how to write an MDD and its corresponding Tcl file.

**Libraries**

The MSS file includes a library block for each library. The library block contains a reference to the library name (LIBRARY_NAME parameter) and the library version (LIBRARY_VER). There is no default value for these parameters. Each library is associated with a processor instance specified using the PROCESSOR_INSTANCE parameter. The library directory contains C source and header files and a make file for the library.
The MLD file for each library specifies all configurable options for the libraries and each MLD file has a corresponding Tcl file.

You can write your own libraries. These libraries must be in a specific directory under `/sw_services` as shown in the figure in Software Repository.

- The `LIBRARY_NAME` attribute lets you specify any name for your libraries, which is also the name of the library directory.
- The source files and make file for the library must be in the `/src` subdirectory under the `/` directory.
- The make file must have the targets `/include` and `/libs`.
- Each library must also contain an MLD file and a Tcl file in the `/data` subdirectory.

Refer to the existing libraries for more information about the structure of the libraries.

Refer to Microprocessor Library Definition (MLD) Overview for details on how to write an MLD and its corresponding Tcl file.

**OS Block**

The MSS file includes an OS block for each processor instance. The OS block contains a reference to the OS name (OS_NAME parameter), and the OS version (OS_VER). There is no default value for these parameters. The bsp directory contains C source and header files and a make file for the OS.

The MLD file for each OS specifies all configurable options for the OS. Each MLD file has a corresponding Tcl file associated with it. Refer to Microprocessor Library Definition (MLD) Overview and MSS Overview.

You can write your own OSs. These OSs must be in a specific directory under `/bsp` or `/bsp` as shown in the figure in Software Repository.

- The `OS_NAME` attribute allows you to specify any name for your OS, which is also the name of the OS directory.
- The source files and make file for the OS must be in the `src` subdirectory under the `/` directory.
- The make file should have the targets `/include` and `/libs`.
- Each OS must contain an MLD file and a Tcl file in the `/data` subdirectory.
Look at the existing OSs to understand the structures. See Microprocessor Library Definition (MLD) Overview for details on how to write an MLD and its corresponding Tcl file, refer to the Device Driver Programmer Guide. This guide is located in your SDK installation, in

<install_directory> \SDK\<version>\data\embeddedsw\doc\xilinx_drivers_guide.pdf.
# Appendix A

## Obsolete Commands

The table below shows the equivalent HSI Tcl commands that are equivalent to obsolete Libgen commands.

Appendix C

BSP, DTS, and Application Generation in Vivado

This chapter demonstrates how to load a .hdf file, access the hardware and software information, and generate BSPs, Applications, and the Device Tree from within Vivado.

1. Run the Vivado hardware handoff flow either in Pre-Synth or Post-Bitstream mode. See the Hardware Handoff section for more information on hardware handoff.

2. Load the hsi feature in Vivado to access all hsi and its util commands as shown below. The hsi:: namespace should be used to access hsi commands.

# Load hsi feature in vivado. After loading the hsi feature, all the hsi commands can be accessed through hsi namespace:

```
Vivado% common::load_feature hsi
```

# Set the software repository path so that driver/bsp/library/applications are available to hsi. Refer to Software Repository section for more information on default and git repositories. If software repository path is not set then only hardware information can be accessed.

```
Vivado% hsi::set_repo_path <software repository path>
```

# Open the hardware design

```
Vivado% hsi::open_hw_design base_zynq_design_wrapper.hdf
```

# Get the processor instances in the design

```
Vivado% hsi::get_cells -filter {IP_TYPE==PROCESSOR}
ps7_cortexa9_0 ps7_cortexa9_1
```
# Get the top level ports in the hardware design

```bash
Vivado% hsi::get_ports
DDR_cas_n DDRcke DDRck_n DDRck_p DDRcs_n DDRreset_n DDRodt DDRras_n DDRwe_n
DDRba DDRaddr DDRdm DDRdq DDRdqs_n DDRdqs_p FIXED_IO_mio
FIXED_IO_ddr_vrn FIXED_IO_ddr_vrp FIXED_IO_ps_srstb FIXED_IO_ps_clk FIXED_IO_ps_porb
leds_4bits_tri_o
```

# Get the list of BSPs available in software repository specified above

```bash
Vivado% hsi::get_sw_cores -filter {TYPE==OS}
freertos820_xilinx_v1_0 standalone_v3_10_a standalone_v3_11_a
standalone_v3_12_a standalone_v4_0 xilkernel_v5_01_a xilkernel_v5_02_a xilkernel_v6_0
standalone_v4_1 xilkernel_v6_1 xilkernel_v6_2 standalone_v5_0 standalone_v4_2 device-tree
```

# Create a software design

```bash
Vivado% hsi::create_sw_design swdesign -proc ps7_cortexa9_0 -os standalone
swdesign
```

# Generate BSP. BSP source code will be dumped to the bsp_out directory

```bash
Vivado% hsi::generate_bsp -dir bsp_out
hsi::generate_bsp: Time (s): cpu = 00:00:00.29 ; elapsed = 00:00:27 .
Memory (MB): peak = 975.637 ; gain = 0.000 ; free physical = 14087 ; free virtual = 135939
Vivado% ls ./bsp_out/ Makefile ps7_cortexa9_0 swdesign.mss
Vivado% ls ./bsp_out/ps7_cortexa9_0/
code include lib libsrc
```

# List of available apps in the repository

```bash
Vivado% hsi::generate_app -lapp
peripheral_tests dhrystone empty_application hello_world lwip_echo_server
memory_tests srec_bootloader ...
```

# Generate a template application. Template application will be dumped to app_out directory

```bash
Vivado% hsi::generate_app -app peripheral_tests -proc ps7_cortexa9_0 -os standalone -dir app_out
hsi::generate_app: Time (s): cpu = 00:00:00.53 ; elapsed = 00:01:16 .
Memory (MB): peak = 975.637 ; gain = 0.000 ; free physical = 14846 ; free virtual = 136743>
Vivado% ls ./app_out/
canps_header.h scugic_header.h xemacps_example_intr_dma.c
devcfg_header.h scutimer_header.h xemacps_example_util.c
```
# Generate Processing System core initialization files. Generated ps_init* are dumped to psinit_out directory

```
Vivado% hsi::generate_target {psinit} [hsi::get_cells -filter [CONFIGURABLE=1]] -dir ./psinit_out
hsi::generate_target: Time (s): cpu = 00:00:08 ; elapsed = 00:00:10 .
Memory (MB): peak = 997.637 ; gain = 22.000 ; free physical = 14785 ; free virtual = 136900
Vivado% ls ./psinit_out/
ps7-init.c ps7-init-gpl.h ps7-init.html ps7-parameters.xml ps7-init-gpl.c ps7-init.h ps7-init.tcl
# Generate Device Tree. Clone device tree repo from GIT
# to ./device-tree-repository/device-tree-generator-master directory.
# Set cloned GIT repo path
Vivado% hsi::set_repo_path ./device_tree_repository/device-tree-generator-master
# create sw design for device tree
Vivado% set proc_name [common::get_property NAME [hsi::get_cells *ps7_cortexa9_0* -filter [IP_TYPE == PROCESSOR]]]
Vivado% hsi::create_sw_design sw_dsgn_device_tree -proc $proc_name -os device_tree
sw_dsgn_device_tree
# generate device tree. Device tree files are dumped to dtg_out directory
Vivado% hsi::generate_target -dir ./device_tree_out
hsi::generate_target: Time (s): cpu = 00:00:04 ; elapsed = 00:00:05 .
Memory (MB): peak = 997.637 ; gain = 0.000 ; free physical = 14731 ; free virtual = 136955
Vivado% ls ./device_tree_out/
pl.dtsi skeleton.dtsi sw_dsgn_device_tree.mss system.dts zynq-7000.dtsi
```
Microprocessor Software Specification (MSS)

MSS Overview
The MSS file contains directives for customizing operating systems (OSs), libraries, and drivers.

MSS Format
An MSS file is case insensitive and any reference to a file name or instance name in the MSS file is also case sensitive. Comments can be specified anywhere in the file. A pound (#) character denotes the beginning of a comment, and all characters after it, right up to the end of the line, are ignored. All white spaces are also ignored and carriage returns act as sentence delimiters.

MSS Keywords
The keywords that are used in an MSS file are as follows:

BEGIN
The keyword begins a driver, processor, or file system definition block. BEGIN should be followed by the driver, processor, or filesys keywords.

END
This keyword signifies the end of a definition block.

PARAMETER
The MSS file has a simple name = value format for statements. The PARAMETER keyword is required before NAME and VALUE pairs. The format for assigning a value to a parameter is parameter name = value. If the parameter is within a BEGIN-END block, it is a local assignment; otherwise it is a global (system level) assignment.
Requirements

The syntax of various files that the embedded development tools use is described by the Platform Specification Format (PSF). The current PSF version is 2.1.0. The MSS file should also contain version information in the form of parameter Version = 2.1.0, which represents the PSF version 2.1.0.

MSS Example

An example MSS file follows:

```
parameter VERSION = 2.1.0

BEGIN OS
parameter PROC_INSTANCE = my_microblaze
parameter OS_NAME = standalone
parameter OS_VER = 1.0
parameter STDIN = my_uartlite_1
parameter STDOUT = my_uartlite_1
END

BEGIN PROCESSOR
parameter HW_INSTANCE = my_microblaze
parameter DRIVER_NAME = cpu
parameter DRIVER_VER = 1.0
parameter XMDSTUB_PERIPHERAL = my_jtag
END

BEGIN DRIVER
parameter HW_INSTANCE = my_intc
parameter DRIVER_NAME = intc
parameter DRIVER_VER = 1.0
END

BEGIN DRIVER
parameter HW_INSTANCE = my_uartlite_1
parameter DRIVER_VER = 1.0
parameter DRIVER_NAME = uartlite
END

BEGIN DRIVER
parameter HW_INSTANCE = my_uartlite_2
parameter DRIVER_VER = 1.0
parameter DRIVER_NAME = uartlite
END

BEGIN DRIVER
parameter HW_INSTANCE = my_timebase_wdt
parameter DRIVER_VER = 1.0
parameter DRIVER_NAME = timebase_wdt
END

BEGIN LIBRARY
parameter LIBRARY_NAME = XilMfs
parameter LIBRARY_VER = 1.0
parameter NUMBYTES = 100000
parameter BASE_ADDRESS = 0x80f00000
END
```
Global Parameters

These parameters are system-specific parameters and do not relate to a particular driver, file system, or library.

PSF Version

This option specifies the PSF version of the MSS file. This option is mandatory, and is formatted as:

\[
\text{parameter VERSION} = 2.1.0
\]

Instance-Specific Parameters

OS, Driver, Library, and Processor Block Parameters

The following list shows the parameters that can be used in OS, driver, library, and processor blocks.

- PROC_INSTANCE
- HW_INSTANCE
- OS_NAME
- OS_VER
- DRIVER_NAME
- DRIVER_VER
- LIBRARY_NAME
- LIBRARY_VER
PROC_INSTANCE

This option is required for the OS associated with a processor instances specified in the hardware database, and is formatted as:

\[
\text{parameter PROC_INSTANCE = <instance_name>}
\]

All operating systems require processor instances to be associated with them. The instance name that is given must match the name specified in the hardware database.

HW_INSTANCE

This option is required for drivers associated with peripheral instances specified in the hardware database and is formatted as:

\[
\text{parameter HW_INSTANCE = <instance_name>}
\]

All drivers in software require instances to be associated with the drivers. Even a processor definition block should refer to the processor instance. The instance name that is given must match the name specified in the BD file.

OS_NAME

This option is needed for processor instances that have OSs associated with them and is formatted as:

\[
\text{parameter OS_NAME = standalone}
\]

OS_VER

The OS version is set using the OSVER option and is formatted as:

\[
\text{parameter OS_VER = 1.0}
\]

This version is specified as \(x.y\), where \(x\) and \(y\) are digits. This is translated to the OS directory searched as follows:

\[
\text{OS_NAME_vx_y}
\]

The MLD (Microprocessor Library Definition) files needed for each OS should be named \text{OS_NAME.mld} and should be present in a subdirectory \text{data/} within the driver directory. Refer to \text{Microprocessor Library Definition (MLD)} for more information.
**DRIVER_NAME**

This option is needed for peripherals that have drivers associated with them and is formatted as:

```
parameter DRIVER_NAME = uartlite
```

Library Generator copies the driver directory specified to the `OUTPUT_DIR/processor_instance_name/lnbsrc` directory and compiles the drivers using makefiles provided.

**DRIVER_VER**

The driver version is set using the `DRIVER_VER` option, and is formatted as:

```
parameter DRIVER_VER = 1.0
```

This version is specified as `x.y`, where `x` and `y` are digits. This is translated to the driver directory searched as follows:

```
DRIVER_NAME_vx_y
```

The MDD (Microprocessor Driver Definition) files needed for each driver should be named `DRIVER_NAME_v2_1_0.mdd` and should be present in a subdirectory `data/` within the driver directory. Refer to Microprocessor Driver Definition (MDD) for more information.

**LIBRARY_NAME**

This option is needed for libraries, and is formatted as:

```
parameter LIBRARY_NAME = xilmfs
```

The tool copies the library directory specified in the `OUTPUT_DIR/processor_instance_name/lnbsrc` directory and compiles the libraries using makefiles provided.

**LIBRARY_VER**

The library version is set using the `LIBRARY_VER` option and is formatted as:

```
parameter LIBRARY_VER = 1.0
```
This version is specified as \(x.y\), where \(x\) and \(y\) are digits. This is translated to the library directory searched by the tool as follows:

\[
\text{LIBRARY_NAME}_v\text{x}_y
\]

The MLD (Microprocessor Library Definition) files needed for each library should be named \text{LIBRARY_NAME}.mld and should be present in a subdirectory \text{data/} within the library directory. Refer to Microprocessor Library Definition (MLD) for more information.

### MLD/MDD Specific Parameters

Parameters specified in the MDD/MLD file can be overwritten in the MSS file and formatted as

\[
\text{parameter PARAM_NAME = PARAM_VALUE}
\]

See Microprocessor Library Definition (MLD) and Microprocessor Driver Definition (MDD) for more information.

### OS—Specific Specific Parameters

The following list identifies all the parameters that can be specified only in an OS definition block.

**STDIN**

Identify the standard input device with the STDIN option, which is formatted as:

\[
\text{parameter STDIN = instance_name}
\]

**STDOUT**

Identify the standard output device with the STDOUT option, which is formatted as:

\[
\text{parameter STDOUT = instance_name}
\]

**Example: MSS Snippet Showing OS Options**

```
BEGIN OS
parameter PROC_INSTANCE = my_microblaze
parameter OS_NAME = standalone
parameter OS_VER = 1.0
parameter STDIN = my_uartlite_1
parameter STDOUT = my_uartlite_1
END
```
Processor—Specific Parameters

Following is a list of all of the parameters that can be specified only in a processor definition block.

**XMDSTUB_PERIPHERAL**

The peripheral that is used to handle the XMDStub should be specified in the XMDSTUB_PERIPHERAL option. This is useful for the MicroBlaze™ processor only, and is formatted as follows:

```
parameter XMDSTUB_PERIPHERAL = instance_name
```

**COMPILER**

This option specifies the compiler used for compiling drivers and libraries. The compiler defaults to `powerpc-eabi-gcc` depending on whether the drivers are part of the MicroBlaze™ processor or PowerPC® processor instance. Any other compatible compiler can be specified as an option, and should be formatted as follows:

```
parameter COMPILER = dcc
```

This example denotes the Diab compiler as the compiler to be used for drivers and libraries.

**ARCHIVER**

This option specifies the utility to be used for archiving object files into libraries. The archiver defaults to `mb-ar` or `powerpc-eabi-ar` depending on whether or not the drivers are part of the MicroBlaze or PowerPC processor instance. Any other compatible archiver can be specified as an option, and should be formatted as follows:

```
parameter ARCHIVER = ar
parameter COMPILER = dcc
```

This example denotes the archiver `ar` to be used for drivers and libraries.

**COMPILER_FLAGS**

This option specifies compiler flags to be used for compiling drivers and libraries. If the option is not specified, the tool automatically uses platform and processor-specific options. This option should not be specified in the MSS file if the standard compilers and archivers are used.

The COMPILER_FLAGS option can be defined in the MSS if there is a need for custom compiler flags that override generated flags.
The `EXTRA_COMPILER_FLAGS` option is recommended if compiler flags must be appended to the ones already generated.

Format this option as follows:

```plaintext
parameter COMPILER_FLAGS = ""
```

**EXTRA_COMPILER_FLAGS**

This option can be used whenever custom compiler flags need to be used in addition to the automatically generated compiler flags, and should be formatted as follows:

```plaintext
parameter EXTRA_COMPILER_FLAGS = -g
```

This example specifies that the drivers and libraries must be compiled with debugging symbols in addition to the generated `COMPILER_FLAGS`.

**Example MSS Snippet Showing Processor Options**

```plaintext
BEGIN PROCESSOR
parameter HW_INSTANCE = my_microblaze
parameter DRIVER_NAME = cpu
parameter DRIVER_VER = 1.00.a
parameter DEFAULT_INIT = xmdstub
parameter XMDSTUB_PERIPHERAL = my_jtag
parameter STDIN = my_uartlite_1
parameter STDOUT = my_uartlite_1
parameter COMPILER = mb-gcc
parameter ARCHIVER = mb-ar
parameter EXTRA_COMPILER_FLAGS = -g -O0
parameter OS = standalone
END
```
Microprocessor Library Definition (MLD)

Microprocessor Library Definition (MLD) Overview

This section describes the Microprocessor Library Definition (MLD) format, Platform Specification Format 2.1.0.

An MLD file contains directives for customizing software libraries and generating Board Support Packages (BSP) for Operating Systems (OS). This document describes the MLD format and the parameters that can be used to customize libraries and OSs.

Requirements

Each OS and library has an MLD file and a Tcl (Tool Command Language) file associated with it. The MLD file is used by the Tcl file to customize the OS or library, depending on different options in the MSS file. For more information on the MSS file format, see Microprocessor Software Specification (MSS).

The OS and library source files and the MLD file for each OS and library must be located at specific directories to find the files and libraries.

MLD Library Definition Files

Library Definition involves defining Data Definition (MLD) and a Data Generation (Tcl) files.

Data Definition File

The MLD file (named as `<library_name>.mld` or `<os_name>.mld`) contains the configurable parameters. A detailed description of the various parameters and the MLD format is described in MLD Parameter Descriptions.
Data Generation File

The second file (named as `<library_name>.tcl` or `<os_name>.tcl`, with the filename being the same as the MLD filename) uses the parameters configured in the MSS file for the OS or library to generate data.

Data generated includes, but is not limited to, header files, C files, DRCs for the OS or library, and executables. The Tcl file includes procedures that are called by the tool at various stages of its execution. Various procedures in a Tcl file include the following:

- **DRC** (the name of the DRC given in the MLD file)
- **generate** (tool defined procedure) called after OS and library files are copied
- **post_generate** (tool defined procedure) called after generate has been called on all OSs, drivers, and libraries
- **execs_generate** (a tool-defined procedure) called after the BSPs, libraries, and drivers have been generated.

*Note:* An OS/library does not require a data generation file (Tcl file).

MLD Format Specification

The MLD format specification involves the MLD file format specification and the Tcl file format specification. The following subsections describe the MLD.

MLD File Format Specification

The MLD file format specification involves the description of configurable parameters in an OS/library. The format used to describe this section is discussed in MLD Parameter Descriptions.

Tcl File Format Specification

Each OS and library has a Tcl file associated with the MLD file. This Tcl file has the following:

**DRC Section:** This section contains Tcl routines that validate your OS and library parameters for consistency.

**Generation Section:** This section contains Tcl routines that generate the configuration header and C files based on the library parameters.
### MLD Design Rule Check Section

```tcl
proc mydrc { handle } { }
```

The DRC function could be any Tcl code that checks your parameters for correctness. The DRC procedures can access (read-only) the Platform Specification Format database (which the tool builds using the hardware (HDF) and software (MSS) database files) to read the parameter values that you set. The handle is associated with the current library in the database. The DRC procedure can get the OS and library parameters from this handle. It can also get any other parameter from the database by first requesting a handle and using the handle to get the parameters.

For errors, DRC procedures call the Tcl error command `error "error msg"` that displays in an error dialog box.

For warnings, DRC procedures return a string value that can be printed on the console.

On success, DRC procedures return without any value.

### MLD Format Examples

This section explains the MLD format through an example MLD file and its corresponding Tcl file.

**Example: MLD File for a Library**

Following is an example of an MLD file for the xilmfs library.

```mld
OPTION psf_version = 2.1.0;
```

`OPTION` is a keyword identified by the tool. The option name following the `OPTION` keyword is a directive to the tool to do a specific action.

The `psf_version` of the MLD file is defined to be 2.1 in this example. This is the only option that can occur before a `BEGIN LIBRARY` construct now.

```mld
BEGIN LIBRARY xilmfs
```

The `BEGIN LIBRARY` construct defines the start of a library named `xilmfs`.

```mld
OPTION DESC = "Xilinx Memory File System";
OPTION drc = mfs_drc;
option copyfiles = all;
OPTION REQUIRES_OS = (standalone xilkernel freertos_zynq);
OPTION VERSION = 2.0;
OPTION NAME = xilmfs;
```
The **NAME** option indicates the name of the driver. The **VERSION** option indicates the version of the driver.

The **COPYFILES** option indicates the files to be copied for the library. The DRC option specifies the name of the Tcl procedure that the tool invokes while processing this library. The `mfs_drc` is the Tcl procedure in the `xilmfs.tcl` file that would be invoked while processing the `xilmfs` library.

```
PARAM name = numbytes, desc = "Number of Bytes", type = int, default = 100000, drc = drc_numbytes ;
PARAM name = base_address, desc = "Base Address", type = int, default = 0x10000, drc = drc_base_address ;
PARAM name = init_type, desc = 'Init Type', type = enum, values = ('New file system'=MFSINIT_NEW, "MFS Image"=MFSINIT_IMAGE, "ROM Image"=MFSINIT_ROM_IMAGE), default = MFSINIT_NEW ;
PARAM name = need_utils, desc = 'Need additional Utilities?', type = bool, default = false ;
```

**PARAM** defines a library parameter that can be configured. Each **PARAM** has the following properties associated with it, whose meaning is self-explanatory: **NAME**, **DESC**, **TYPE**, **DEFAULT**, **RANGE**, **DRC**. The property **VALUES** defines the list of possible values associated with an **ENUM** type.

```
BEGIN INTERFACE file
  PROPERTY HEADER="xilmfs.h" ;
  FUNCTION NAME=open, VALUE=mfs_file_open ;
  FUNCTION NAME=close, VALUE=mfs_file_close ;
  FUNCTION NAME=read, VALUE=mfs_file_read ;
  FUNCTION NAME=write, VALUE=mfs_file_write ;
  FUNCTION NAME=lseek, VALUE=mfs_file_lseek ;
END INTERFACE
```

An Interface contains a list of standard functions. A library defining an interface should have values for the list of standard functions. It must also specify a header file where all the function prototypes are defined.

**PROPERTY** defines the properties associated with the construct defined in the **BEGIN** construct. **HEADER** is a property with value `xilmfs.h`, defined by the file interface. **FUNCTION** defines a function supported by the interface.

The **open**, **close**, **read**, **write**, and **lseek** functions of the file interface have the values `mfs_file_open`, `mfs_file_close`, `mfs_file_read`, `mfs_file_write`, and `mfs_file_lseek`. These functions are defined in the header file `xilmfs.h`.

```
BEGIN INTERFACE filesystem
```

---

**Appendix E: Microprocessor Library Definition (MLD)**

*[Xilinx documentation]*

---

**UG1138 (v2019.1) May 22, 2019**

*[Xilinx website]*

---

**Send Feedback**
BEGIN INTERFACE defines an interface the library supports. Here, file is the name of the interface.

```
PROPERTY HEADER="xilmfs.h" ;
FUNCTION NAME=cd, VALUE=mfs_change_dir ;
FUNCTION NAME=opendir, VALUE=mfs_dir_open ;
FUNCTION NAME=closedir, VALUE=mfs_dir_close ;
FUNCTION NAME=readdir, VALUE=mfs_dir_read ;
FUNCTION NAME=readdir, VALUE=mfs_delete_dir ;
FUNCTION NAME=pwd, VALUE=mfs_get_current_dir_name ;
FUNCTION NAME=rename, VALUE=mfs_rename_file ;
FUNCTION NAME=exists, VALUE=mfs_exists_file ;
FUNCTION NAME=delete, VALUE=mfs_delete_file ;
END INTERFACE
```

END is used with the construct name that was used in the BEGIN statement. Here, END is used with INTERFACE and LIBRARY constructs to indicate the end of each of INTERFACE and LIBRARY constructs.

**Example: Tcl File of a Library**

The following is the xilmfs.tcl file corresponding the xilmfs.mld file described in the previous section. The mfs_drc procedure would be invoked for the xilmfs library while running DRCs for libraries. The generate routine generates constants in a header file and a c file for the xilmfs library based on the library definition segment in the MSS file.

```
proc mfs_drc {lib_handle} {
    puts 'MFS DRC ...'
}

proc mfs_open_include_file {file_name} {
    set filename [file join ../../include/ $file_name]
    if {[file exists $filename]} {
        set config_inc [open $filename a]
    } else {
        set config_inc [open $filename a]
        ::hsi::utils::write_c_header $config_inc "MFS Parameters"
    }
    return $config_inc
}

proc generate {lib_handle} {
    puts 'MFS generate ...'
    file copy 'src/xilmfs.h' ../../include/xilmfs.h'
    set conffile [mfs_open_include_file "mfs_config.h"]
    puts $conffile "#ifndef _MFS_CONFIG_H"
    puts $conffile "#define _MFS_CONFIG_H"
    set need Utils [common::get_property CONFIG.need_utils $lib_handle]
    if {$need_utils} {
        # tell libgen or xps that the hardware platform needs to provide
        # inbyte and outbyte to support utils
    
```

Appendix E: Microprocessor Library Definition (MLD)

UG1138 (v2018.2) July 16, 2018  www.xilinx.com  [placeholder text]

Generating Basic Software Platforms  62

Send Feedback
Example: MLD File for an OS

An example of an MLD file for the standalone OS is given below:

```plaintext
OPTION psf_version = 2.1.0 ;

OPTION is a keyword identified by the tool. The option name following the OPTION keyword is a directive to the tool to do a specific action. Here the psf_version of the MLD file is defined to be 2.1. This is the only option that can occur before a BEGIN OS construct at this time.

BEGIN OS standalone

The BEGIN OS construct defines the start of an OS named standalone.

OPTION DESC = 'Generate standalone BSP';
OPTION COPYFILES = all;

The DESC option gives a description of the MLD. The COPYFILES option indicates the files to be copied for the OS.

PARAM NAME = stdin, DESC = 'stdin peripheral ', TYPE = peripheral_instance, REQUIRES_INTERFACE = stdin, DEFAULT = none; PARAM
NAME = stdout, DESC = 'stdout peripheral ', TYPE = peripheral_instance, REQUIRES_INTERFACE = stdout, DEFAULT = none ; PARAM NAME = need_xilmalloc,
DESC = 'Need xil_malloc?', TYPE = bool, DEFAULT = false ;

PARAM defines an OS parameter that can be configured. Each PARAM has the following, associated properties: NAME, DESC, TYPE, DEFAULT, RANGE, DRC. The property VALUES defines the list of possible values associated with an ENUM type.

END OS

END is used with the construct name that was used in the BEGIN statement. Here END is used with OS to indicate the end of OS construct.
Example: Tcl File of an OS

The following is the `standalone.tcl` file corresponding to the `standalone.mld` file described in the previous section. The `generate` routine generates constants in a header file and a `c` file for the xilmfs library based on the library definition segment in the MSS file.

```tcl
proc generate {os_handle} {
    global env
    set need_config_file "false"

    # Copy over the right set of files as src based on processor type
    set sw_proc_handle [get_sw_processor]
    set hw_proc_handle [get_cells [get_property HW_INSTANCE $sw_proc_handle]]
    set proctype [get_property IP_NAME $hw_proc_handle]
    set procname [get_property NAME $hw_proc_handle]

    set enable_sw_profile [get_property CONFIG.enable_sw_intrusive_profiling $os_handle]
    set mb_exceptions false

    switch $proctype {
        'microblaze' {
            foreach entry [glob -nocomplain [file join $mbsrcdir *]] {
                # Copy over only files that are not related to exception handling.
                file copy -force $entry ".src/"
            }
            set need_config_file 'true'
            set mb_exceptions [mb_has_exceptions $hw_proc_handle]
        }
        'ps7_cortexa9' {
            set procdrv [get_sw_processor]
            set compiler [get_property CONFIG.compiler $procdrv]
            if {[string compare -nocase $compiler "armcc"] == 0} {
                set ccdir "/src/cortexa9/armcc"
                file copy -force $entry ".src/"
            } else {
                set ccdir "/src/cortexa9/gcc"
            }
            foreach entry [glob -nocomplain [file join $cortexa9srcdir *]] {
                file copy -force $entry ".src/"
            }
        }

        file delete -force "/src/armcc"
        file delete -force "/src/gcc"
        if {[string compare -nocase $compiler "armcc"] == 0} {
            file delete -force "/src/profile"
            set enable_sw_profile "false"
        }
        set file_handle [xopen_include_file "xparameters.h"]
        puts "$file_handle "#include \"xparameters_ps.h\""
    }
```
MLD Parameter Descriptions

MLD Parameter Description Section

This section gives a detailed description of the constructs used in the MLD file.

Conventions

[] Denotes optional values.

<> Value substituted by the MLD writer.

Comments

Comments can be specified anywhere in the file. A “#” character denotes the beginning of a comment and all characters after the “#” right up to the end of the line are ignored. All white spaces are also ignored and semi-colons with carriage returns act as sentence delimiters.

OS or Library Definition

The OS or library section includes the OS or library name, options, dependencies, and other global parameters, using the following syntax:

```
OPTION psf_version = <psf version number> BEGIN LIBRARY/OS <library/os name> [OPTION drc = <global drc name>] [OPTION depends = <list of directories>] [OPTION help = <help file>] [OPTION requires_interface = <list of interface names>] PARAM <parameter description> [BEGIN CATEGORY <name of category> <category description> END CATEGORY] BEGIN INTERFACE <interface name> ....... END INTERFACE END LIBRARY/OS
```

MLD Keywords

The keywords that are used in an MLD file are as follows:

BEGIN

The BEGIN keyword begins one of the following: os, library, driver, block, category, interface, array.
END

The END keyword signifies the end of a definition block.

PSF_VERSION

Specifies the PSF version of the library.

DRC

Specifies the DRC function name. This is the global DRC function, which is called by the GUI configuration tool or the command-line tool. This DRC function is called once you enter all the parameters and MLD or MDD writers can verify that a valid OS, library, or driver can be generated with the given parameters.

OPTION

Specifies that the name following the keyword option is an option to the GUI tools.

OS

Specifies the type of OS. If it is not specified, then OS is assumed as standalone type of OS.

COPYFILES

Specifies the files to be copied for the OS, library, or driver. If ALL is used, then the tool copies all the OS, library, or driver files.

DEPENDS

Specifies the list of directories that needs to be compiled before the OS or library is built.

SUPPORTED_PERIPHERALS

Specifies the list of peripherals supported by the OS. The values of this option can be specified as a list, or as a regular expression. For example:

```plaintext
option supported_peripherals = (microblaze)
```

Indicates that the OS supports all versions of microblaze. Regular expressions can be used in specifying the peripherals and versions. The regular expression (RE) is constructed as follows:

- Single-Character REs:
  - Any character that is not a special character (to be defined) matches itself.
A backslash (followed by any special character) matches the literal character itself. That is, this "escapes" the special character.

The special characters are: + * ? . [ ] ^ $

The period (.) matches any character except the new line. For example, .umpty matches both Humpt and Dumpt.

A set of characters enclosed in brackets ([ ]) is a one-character RE that matches any of the characters in that set. For example, [a-km] matches either an "a", "k", or "m".

A range of characters can be indicated with a dash. For example, [a-z] matches any lower-case letter. However, if the first character of the set is the caret (^), then the RE matches any character except those in the set. It does not match the empty string. Example: [^a-km] matches any character except "a", "k", or "m". The caret loses its special meaning if it is not the first character of the set.

Multi-Character REs:

- A single-character RE followed by an asterisk (*) matches zero or more occurrences of the RE. Thus, [a-z]* matches zero or more lower-case characters.
- A single-character RE followed by a plus (+) matches one or more occurrences of the RE. Thus, [a-z]+ matches one or more lower-case characters.
- A question mark (?) is an optional element. The preceding RE can occur zero or once in the string, no more. Thus, xy?z matches either xyz or xz.
- The concatenation of REs is a RE that matches the corresponding concatenation of strings. For example, [A-Z][a-z]* matches any capitalized word.
- For example, the following matches a version of the axidma:

```
OPTION supported_peripherals = (axi_dma_v[3-9]_[0-9][0-9]_[a-z] axi_dma_v[3-9]_[0-9]);
```

LIBRARY_STATE

Specifies the state of the library. Following is the list of values that can be assigned to LIBRARY_STATE:

- **ACTIVE**: An active library. By default the value of LIBRARY_STATE is ACTIVE.
- **DEPRECATED**: This library is deprecated
- **OBSOLETE**: This library is obsolete and will not be recognized by any tools. Tools error out on an obsolete library and a new library should be used instead.
**APP_COMPILER_FLAGS**

This option specifies what compiler flags must be added to the application when using this library. For example:

```
OPTION APP_COMPILER_FLAGS = "-D MYLIBRARY"
```

The GUI tools can use this option value to automatically set compiler flags automatically for an application.

**APP_LINKER_FLAGS**

This option specifies that linker flags must be added to the application when using a particular library or OS. For example:

```
OPTION APP_LINKER_FLAGS = "-lxilkernel"
```

The GUI tools can use this value to set linker flags automatically for an application.

**BSP**

Specifies a boolean keyword option that can be provided in the MLD file to identify when an OS component is to be treated as a third party BSP. For example:

```
OPTION BSP = true;
```

This indicates that the SDK tools will offer this OS component as a board support package. If set to false, the component is handled as a native embedded software platform.

**OS_STATE**

Specifies the state of the operating system (OS). Following is the list of values that can be assigned to OS_STATE:

- **ACTIVE**: This is an active OS. By default the value of OS_STATE is ACTIVE.
- **DEPRECATED**: This OS is deprecated.
- **OBSOLETE**: This OS is obsolete and will not be recognized by the tools. Tools error out on an obsolete OS and a new OS must be specified.

**OS_TYPE**

Specifies the type of OS. This value is matched with SUPPORTED_OS_TYPES of the driver MDD file for assigning the driver. Default is standalone.
**REQUIRES_INTERFACE**

Specifies the interfaces that must be provided by other OSs, libraries, or drivers in the system.

**REQUIRES_OS**

Specifies the list of OSs with which the specified library will work. For example:

```bash
OPTION REQUIRES_OS = (standalone xilkernel_v4_[0-9][0-9])
```

The GUI tools use this option value to determine which libraries are offered for a given operating system choice. The values in the list can be regular expressions as shown in the example.

**Note:** This option must be used on libraries only.

**HELP**

Specifies the HELP file that describes the OS, library, or driver.

**DEP**

Specifies the condition that must be satisfied before processing an entity. For example to include a parameter that is dependent on another parameter (defined as a DEP, for dependent, condition), the DEP condition should be satisfied. Conditions of the form (operand1 OP operand2) are the only supported conditions.

**INTERFACE**

Specifies the interfaces implemented by this OS, library, or driver. It describes the interface functions and header files used by the library/driver.

```bash
BEGIN INTERFACE <interface name>
  OPTION DEP=;<list of dependencies>:
  PROPERTY HEADER=<name of header file where the function is declared>:
  FUNCTION NAME=<name of the interface function>, VALUE=<function name of library/driver implementation>:
END INTERFACE
```

**HEADER**

Specifies the HEADER file in which the interface functions would be defined.

**FUNCTION**

Specifies the FUNCTION implemented by the interface. This is a name-value pair in which name is the interface function name and value is the name of the function implemented by the OS, library, or driver.
CATEGORY

Defines an unconditional block. This block gets included based on the default value of the category or if included in the MSS file.

```
BEGIN CATEGORY <category name>
    PARAM name = <category name>, DESC=<param description>,
    TYPE=<category type>,
    DEFAULT=<default>, GUI_PERMIT=<value>, DEP = <condition>
    OPTION DEPENDS=<list of dependencies>, DRC=<drc name>, HELP=<help
file>:
    <parameters or categories description>
END CATEGORY
```

Nested categories are not supported through the syntax that specifies them. A category is selected in a MSS file by specifying the category name as a parameter with a boolean value TRUE. A category must have a PARAM with category name.

PARAM

The MLD file has a simple <name = value> format for most statements. The PARAM keyword is required before every such NAME, VALUE pair. The format for assigning a value to a parameter is param name = <name>, default = value. The PARAM keyword specifies that the parameter can be overwritten in the MSS file.

PROPERTY

Specifies the various properties of the entity defined with a BEGIN statement.

NAME

Specifies the name of the entity in which it was defined. (Examples: param and property.) It also specifies the name of the library if it is specified with option.

VERSION

Specifies the version of the library.

DESC

Describes the entity in which it was defined. (Examples: param and property.)

TYPE

Specifies the type for the entity in which it was defined. (Example: param.) The following types are supported:

- **bool**: Boolean (true or false)
• int: Integer
• string: String value within " " (quotes)
• enum: List of possible values that a parameter can take
• library: Specify other library that is needed for building the library/driver
• peripheral_instance: Specify other hardware drivers that is needed for building the library

DEFAULT

Specifies the default value for the entity in which it was defined.

GUI_PERMIT

Specifies the permissions for modification of values. The following permissions exist:

• NONE: The value cannot be modified at all.
• ADVANCED_USER: The value can be modified by all. The SDK GUI does not display this value by default. This is displayed only for the advanced option in the GUI.
• ALL_USERS: The value can be modified by all. The SDK GUI displays this value by default. This is the default value for all the values. If GUI_PERMIT = NONE, the category is always active.

ARRAY

ARRAY can have any number of PARAMs, and only PARAMs. It cannot have CATEGORY as one of the fields of an array element. The size of the array can be defined as one of the properties of the array. An array with default values specified in the default property leads to its size property being initialized to the number of values. If there is no size property defined, a size property is created before initializing it with the default number of elements. Each parameter in the array can have a default value. In cases in which size is defined with an integer value, an array of size elements would be created wherein the value of each element would be the default value of each of the parameters.

BEGIN ARRAY <array name>
  PROPERTY desc = <array description> ;
  PROPERTY size = <size of the array> ;
  PROPERTY default = <List of Values for each element based on the size of the array>
  # array field description as parameters
  PARAM name = <name of parameter>, desc = 'description of param',
              type = <type of param>, default = <default value>
    .......
END ARRAY
MLD Design Rule Check Section

```tcl
proc mydrc { handle } { }
```

The DRC function could be any Tcl code that checks your parameters for correctness. The DRC procedures can access (read-only) the Platform Specification Format database (which the tool builds using the hardware (HDF) and software (MSS) database files) to read the parameter values that you set. The handle is associated with the current library in the database. The DRC procedure can get the OS and library parameters from this handle. It can also get any other parameter from the database by first requesting a handle and using the handle to get the parameters.

For errors, DRC procedures call the Tcl error command `error "error msg"` that displays in an error dialog box.

For warnings, DRC procedures return a string value that can be printed on the console.

On success, DRC procedures return without any value.

MLD Tool Generation (Generate) Section

```tcl
proc mygenerate { handle } {
}
```

Generate could be any Tcl code that reads your parameters and generates configuration files for the OS or library. The configuration files can be C files, Header files, Makefiles, etc. The generate procedures can access (read-only) the Platform Specification Format database (which the tool builds using the MSS files) to read the parameter values of the OS or library that you set. The handle is a handle to the current OS or library in the database. The generate procedure can get the OS or library parameters from this handle. It can also get any other parameter from the database by first requesting a handle and using the handle to get the parameter.
Microprocessor Driver Definition (MDD)

Microprocessor Driver Definition (MDD) Overview

This chapter describes the Microprocessor Driver Definition (MDD) format, Platform Specification Format 2.1.0.

An MDD file contains directives for customizing software drivers. This document describes the MDD format and the parameters that can be used to customize drivers.

Requirements

Each device driver has an MDD file and a Tool Command Language (Tcl) file associated with it. The MDD file is used by the Tcl file to customize the driver, depending on different options configured in the MSS file. For more information on the MSS file format, see Microprocessor Software Specification (MSS).

The driver source files and the MDD file for each driver must be located at specific directories in order to find the files and the drivers.

MDD Driver Definition Files

Driver Definition involves defining a Data Definition file (MDD) and a Data Generation file (Tcl file).

- **Data Definition File**: The MDD file (<driver_name>.mdd) contains the configurable parameters. A detailed description of the parameters and the MDD format is described in MDD Parameter Description.
Data Generation File: The second file (<driver_name>.tcl), with the filename being the same as the MDD filename) uses the parameters configured in the MSS file for the driver to generate data. Data generated includes but is not limited to generation of header files, C files, running DRCs for the driver, and generating executables. The Tcl file includes procedures that are called by the tool at various stages of its execution.

Various procedures in a Tcl file includes: the DRC (name of the DRC given in the MDD file), generate (tool defined procedure) called after driver files are copied, post_generate (tool defined procedure) called after generate has been called on all drivers and libraries, and execs_generate called after the libraries and drivers have been generated.

Note: A driver does not require the data generation file (Tcl file).

MDD Format Specification

The MDD format specification involves the MDD file Format specification and the Tcl file Format specification which are described in the following subsections.

MDD File Format Specification

The MDD file format specification describes the parameters defined in the Parameter Description section. This data section describes configurable parameters in a driver. The format used to describe these parameters is discussed in MDD Parameter Description.

Tcl File Format Specification

Each driver has a Tcl file associated with the MDD file. This Tcl file has the following sections:

- **DRC Section**: This section contains Tcl routines that validate your driver parameters for consistency.
- **Generation Section**: This section contains Tcl routines that generate the configuration header and C files based on the driver parameters.

MDD Format Examples

This section explains the MDD format through an example of an MDD file and its corresponding Tcl file.
Example: MDD File

The following is an example of an MDD file for the uartlite driver.

```
OPTION psf_version = 2.1;
```

**OPTION** is a keyword identified by the tool. The option name following the **OPTION** keyword is a directive to the tool to do a specific action. Here the **psf_version** of the MDD file is defined as 2.1. This is the only option that can occur before a **BEGIN DRIVER** construct.

```
BEGIN DRIVER uartlite
```

The **BEGIN DRIVER** construct defines the start of a driver named uartlite.

```
OPTION supported_peripherals = (mdm axi_uartlite);
OPTION driver_state = ACTIVE;
OPTION copyfiles = all;
OPTION VERSION = 3.0;
OPTION NAME = uartlite;
```

The **NAME** option indicates the name of the driver. The **VERSION** option indicates the version of the driver. The **COPYFILES** option indicates the files to be copied for a “level” 0 uartlite driver.

```
BEGIN INTERFACE stdin
```

**BEGIN INTERFACE** defines an interface the driver supports. The interface name is **stdin**.

```
PROPERTY header = xuartlite_l.h;
FUNCTION name = inbyte, value = XUartLite_RecvByte;
END INTERFACE
```

An Interface contains a list of standard functions. A driver defining an interface should have values for the list of standard functions. It must also specify a header file in which all the function prototypes are defined.

**PROPERTY** defines the properties associated with the construct defined in the **BEGIN** construct. The header is a property with the value **xuartlite_l.h**, defined by the **stdin** interface. **FUNCTION** defines a function supported by the interface. The inbyte function of the stdin interface has the value **XUartLite_RecvByte**. This function is defined in the header file **xuartlite_l.h**.

```
BEGIN INTERFACE stdout

PROPERTY header = xuartlite_l.h;
FUNCTION name = outbyte, value = XUartLite_SendByte;
END INTERFACE
```
BEGIN INTERFACE stdio
PROPERTY header = xuartlite_l.h;
FUNCTION name = inbyte, value = XUartLite_RecvByte;
FUNCTION name = outbyte, value = XUartLite_SendByte;
END INTERFACE

END is used with the construct name that was used in the BEGIN statement. Here END is used with BLOCK and DRIVER constructs to indicate the end of each BLOCK and DRIVER construct.

Example: Tcl File

The following is the uartlite.tcl file corresponding to the uartlite.mdd file described in the previous section. The “uartlite_drc” procedure would be invoked for the uartlite driver while running DRCs for drivers. The generate routine generates constants in a header file and a c file for uartlite driver, based on the driver definition segment in the MSS file.

```
proc generate {drv_handle} {
    ::hsi::utils::define_include_file $drv_handle "xparameters.h"
    "XUartLite" "NUM_INSTANCES" "C_BASEADDR"
    "C_HIGHADDR" "DEVICE_ID" "C_BAUDRATE" "C_USE_PARITY" "C_ODD_PARITY"
    "C_DATA_BITS"
    ::hsi::utils::define_config_file $drv_handle "xuartlite_g.c"
    "XUartLite" "DEVICE_ID" "C_BASEADDR"
    "C_BAUDRATE" "C_USE_PARITY" "C_ODD_PARITY" "C_DATA_BITS"
    ::hsi::utils::define_canonical_xpars $drv_handle "xparameters.h"
    "UartLite" "DEVICE_ID" "C_BASEADDR"
    "C_HIGHADDR" "C_BAUDRATE" "C_USE_PARITY" "C_ODD_PARITY" "C_DATA_BITS"
}
```

MDD Parameter Description

This section gives a detailed description of the constructs used in the MDD file.

Conventions

[ ]: Denotes optional values.

<>: Value substituted by the MDD writer.

Comments

Comments can be specified anywhere in the file. A pound (#) character denotes the beginning of a comment, and all characters after it, right up to the end of the line, are ignored. All white spaces are also ignored and semicolons with carriage returns act as sentence delimiters.
Driver Definition

The driver section includes the driver name, options, dependencies, and other global parameters, using the following syntax:

```plaintext
OPTION psf_version = <psf version number>
BEGIN DRIVER <driver name>
  [OPTION drc = <global drc name>]
  [OPTION depends = <list of directories>]
  [OPTION help = <help file>]
  [OPTION requires_interface = <list of interface names>]
PARAM <parameter description>
  [BEGIN BLOCK, dep = <condition>]
      .......
  END BLOCK]
  [BEGIN INTERFACE <interface name>]
      .......
  END INTERFACE]
END DRIVER
```

MDD Keywords

The keywords that are used in an MDD file are as follows:

BEGIN

The `BEGIN` keyword begins with one of the following: `library, drive, block, category, or interface`.

END

The `END` keyword signifies the end of a definition block.

PSF_VERSION

Specifies the PSF version of the library.

DRC

Specifies the DRC function name. This is the global DRC function that is called by the GUI configuration tool or the command line tool. This DRC function is called when you enter all the parameters and the MLD or MDD writers can verify that a valid library or driver can be generated with the given parameters.
OPTION

Specifies the name following the keyword OPTION is an option to the tool. The following five options are supported: COPYFILES, DEPENDS, SUPPORTED_PERIPHERALS, and DRIVER_STATE.

SUPPORTED_OS_TYPES

Specifies the list of supported OS types. If it is not specified, then driver is assumed as standalone driver.

COPYFILES

Specifies the list of files to be copied for the driver. If ALL is specified as the value, the tool copies all the driver files.

DEPENDS

Specifies the list of directories on which a driver depends for compilation.

SUPPORTED_PERIPHERALS

Specifies the list of peripherals supported by the driver. The values of this option can be specified as a list or as a regular expression. The following example indicates that the driver supports all versions of opb_jtag_uart and the opb_uartlte_v1_00_b version:

```
option supported_peripherals = (xps_uartlite_v1_0, xps_uart16550)
```

Regular expressions can be used in specifying the peripherals and versions. The regular expression (RE) is constructed as described below.

Single-Character REs:

- Any character that is not a special character (to be defined) matches itself.
- A backslash (followed by any special character) matches the literal character itself. That is, it escapes the special character.
- The special characters are: + * ? . [ ] ^ $
- The period matches any character except the newline. For example, .umpty matches both Humpty and Dumpty.
- A set of characters enclosed in brackets ([ ] ) is a one-character RE that matches any of the characters in that set. For example, [akm] matches an a, k, or m. A range of characters can be indicated with a dash. For example, [a-z] matches any lower-case letter.
However, if the first character of the set is the caret (^), then the RE matches any character except those in the set. It does not match the empty string. For example,[^akm] matches any character except a, k, or m. The caret loses its special meaning if it is not the first character of the set.

Multi-Character REs:

- A single-character RE followed by an asterisk (*) matches zero or more occurrences of the RE. Therefore, [a-z]* matches zero or more lower-case characters.
- A single-character RE followed by a plus (+) matches one or more occurrences of the RE. Therefore, [a-z]+ matches one or more lower-case characters.
- A question mark (?) is an optional element. The preceding RE can occur no times or one time in the string. For example, xy?z matches either xyz or xz.
- The concatenation of REs is an RE that matches the corresponding concatenation of strings. For example, [A-Z][a-z]* matches any capitalized word.

The following example matches any version of xps_uartlite, xps_uart16550, and mdm.

```plaintext
OPTION supported_peripherals = (xps_uartlite_v[0-9]+_[1-9][0-9]_[a-z]
xps_uart16550 mdm):
```

**DRIVER_STATE**

Specifies the state of the driver. The following are the list of values that can be assigned to DRIVER_STATE:

- **ACTIVE**: This is an active driver. By default the value of DRIVER_STATE is ACTIVE.
- **DEPRECATED**: This driver is deprecated and is scheduled to be removed.
- **OBSOLETE** This driver is obsolete and is not recognized by any tools. Tools error out on an obsolete driver, and a new driver should be used instead.

**REQUIRES_INTERFACE**

Specifies the interfaces that must be provided by other libraries or drivers in the system.

**HELP**

Specifies the help file that describes the library or driver.

**DEP**

Specifies the condition that needs to be satisfied before processing an entity. For example, to enter into a BLOCK, the DEP condition should be satisfied. Conditions of the form ( operand1 OP operand2) are supported.
BLOCK

Specifies the block is to be entered into when the `DEP` condition is satisfied. Nested blocks are not supported.

INTERFACE

Specifies the interfaces implemented by this library or driver and describes the interface functions and header files used by the library or driver.

```
BEGIN INTERFACE <interface name>
  OPTION DEP=<list of dependencies>;
  PROPERTY HEADER=<name of header file where the function is declared> ;
  FUNCTION NAME=<name of interface function>, VALUE=<function name of library/driver implementation> ;
END INTERFACE
```

HEADER

Specifies the header file in which the interface functions would be defined.

FUNCTION

Specifies the function implemented by the interface. This is a name-value pair where `name` is the interface function name and `value` is the name of the function implemented by the library or driver.

PARAM

Generally, the MLD/MDD file has a `name = value` format for statements. The PARAM keyword is required before every such `NAME, VALUE` pair. The format for assigning a value to a parameter is `param name = <name>`, default= `value`. The PARAM keyword specifies that the parameter can be overwritten in the MSS file.

DTGPARAM

The DTGPARAM keyword is specially used for the device-tree specific parameters that can be configured. Driver defines these DTGPARAMs if it needs to dump any parameters in the Tool DTG generated DTS file.

PROPERTY

Specifies the various properties of the entity defined with a BEGIN statement.
NAME
Specifies the name of the entity in which it was defined (example: `PARAM`, `PROPERTY`). It also specifies the name of the driver if it is specified with option.

VERSION
Specifies the version of the driver.

DESC
Describes the entity in which it was defined (example: `PARAM`, `PROPERTY`).

TYPE
Specifies the type for the entity in which it was defined (example: `PARAM`). The following are the supported types:

- `bool`: Boolean (true or false)
- `int`: Integer
- `string`: String value within " " (quotes).
- `enum`: List of possible values, that this parameter can take.
- `library`: Specify other library that is needed for building the library or driver.
- `peripheral_instance`: Specify other hardware drivers needed for building the library or driver. Regular expressions can be used to specify the peripheral instance. Refer to `SUPPORTED_PERIPHERALS` for more details about regular expressions.

DEFAULT
Specifies the default value for the entity in which it was defined.

GUI_PERMIT
Specifies the permissions for modification of values. The following permissions exist:

- `NONE`: The value can not be modified at all.
- `ADVANCED_USER`: The value can be modified by all. The SDK GUI does not display this value by default. It is displayed only as an advanced option in the GUI.
- `ALL_USERS`: The value can be modified by all. The SDK GUI displays this value by default. This is the default value for all the values. If `GUI_PERMIT` = `NONE`, the category is always active.
MDD Design Rule Check (DRC) Section

```tcl
proc mydrc { handle }
```

The DRC function can be any Tcl code that checks your parameters for correctness. The DRC procedures can access (read-only) the Platform Specification Format database (built by the tool using the hardware (HDF) and software (MSS) database files) to read the parameter values you set. The "handle" is a handle to the current driver in the database. The DRC procedure can get the driver parameters from this handle. It can also get any other parameter from the database by first requesting a handle and then using the handle to get the parameters.

- For errors, DRC procedures call the Tcl error command `error "error msg"` that displays in an error dialog box.
- For warnings, DRC procedures return a string value that can be printed on the console.
- On success, DRC procedures just return without any value.

MDD Driver Generation (Generate) Section

```tcl
proc mygenerate { handle }
```

generate could be any Tcl code that reads your parameters and generates configuration files for the driver. The configuration files can be C files, Header files, or Makefiles.

The generate procedures can access (read-only) the Platform Specification Format database (built by the tool using the MSS files) to read the parameter values of the driver that you set.

The handle is a handle to the current driver in the database.

The generate procedure can get the driver parameters from this handle. It can also get any other parameters from the database by requesting a handle and then using the handle to get the parameter.
Custom Driver

This section demonstrates how to handoff a custom driver associated with an IP (driver files are specified in IPXACT file of the IP component) and access the driver information in HSI as well as associate the driver with IP during BSP generation. For more information on packaging IP with custom driver, refer to Vivado Design Suite User Guide: Creating and Packaging Custom IP (UG1118).

Figure 6: Example Design with an IP with custom driver

The figure above shows an example design of an IP with custom driver specified in its IPXACT definition.
Figure 7: Custom driver specified in IPXACT specification of an IP

Run Vivado hardware handoff flow either in Pre-Synth or Post-Bitstream mode. Refer to Hardware Handoff section for more information. Custom driver for each IP is packaged in HDF.

# Open the hardware design with custom drivers.

```bash
hsi::open_hw_design ./base_zynq_design_wrapper.hdf
base_zynq_design_wrapper
```

# Create a software design

```bash
hsi::create_sw_design swdesign -proc ps7_cortexa9_0 -os standalone
Swdesign
```

# Check if the custom drivers are assign to respective IP cores or not

```bash
join [hsi::get_drivers ] \naxi_bram_ctrl_0
axi_gpio_0
myip_0
```
# Check the custom driver properties

```c
common::report_property [ hsi::get_drivers myip*]
```

Microprocessor Application Definition (MAD)

Microprocessor Application Definition (MAD) Overview

A MAD file contains directives for customizing software application. This section describes the Microprocessor Application Definition (MAD) format, Platform Specification Format 2.1.0. and the parameters that can be used to customize applications.

Requirements

Each application has an MAD file and a Tool Command Language (Tcl) file associated with it.

The MAD file is used by Hsi to recognize it as an application and to consider its configuration while generating the application sources. The MAD file for each application must be located in its data directory.

Microprocessor Application Definition Files

Application Definition involves defining a Microprocessor Application Definition file (MAD) and a Data Generation file (Tcl file).

Application Definition File

The MAD file (<application_name>.mad) contains the name, description, and other configurable parameters. A detailed description of the various parameters and the MAD format is described in MAD Format Specification.

Data Generation File

The second file (<application_name>.tcl, with the filename being the same as the MAD filename) uses the parameters in the MAD file for the application to generate data.
Data generated includes, but is not limited to, generation of header files, C files, running DRCs for the application, and generating executables. The Tcl file includes procedures that are called by the tool at various stages of its execution. Various procedures in a Tcl file includes the following:

- **DRC** (swapp_is_supported_hw, swapp_is_supported_sw)
- **swapp_generate** (tool defined procedure) called after application source files are copied

---

**MAD Format Specification**

The MAD format specification involves the MAD file format specification and the Tcl file format specification.

**MAD File Format Specification**

The MAD file format specification describes the parameters using a sample MAD file and its corresponding Tcl file.

The following example shows a MAD file for a sample application called my_application.

```plaintext
OPTION psf_version = 2.1;

BEGIN APPLICATION my_application

OPTION NAME = myapplication
OPTION DESCRIPTION = "My custom application"

END APPLICATION
```

*Note:* The application NAME should match the return value of the Tcl process swapp_get_name in the application Tcl file described above.

**Tcl File Format Specification**

Each application has a Tcl file associated with the MAD file. This Tcl file has the following sections:
• **DRC Section**: This section contains Tcl routines that validate your hardware and software instances and their configuration needed for the application.

• **Generation Section**: This section contains Tcl routines that generate the application header and C files based on the hardware and software configuration.

---

**MAD Format Example**

This section explains the MAD format through an example MAD file and its corresponding Tcl file.

**Example: MAD File**

The following is an example of an MAD file for a sample application called my_application.

```plaintext
OPTION psf_version = 2.1;

BEGIN APPLICATION my_application

OPTION NAME = myapplication
OPTION DESCRIPTION = "My custom application"
END APPLICATION
```

**Note:** Application NAME should match the return value of Tcl proc swapp_get_name in application Tcl file described above.
Appendix H

Tcl Commands Listed Alphabetically

This section contains all Hardware Software Interface Tcl commands, arranged alphabetically.

common::create_property

Create property for class of objects(s).

Syntax

```tcl
```

Returns

The property that was created if success, "" if failure

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-description</code></td>
<td>Description of property</td>
</tr>
<tr>
<td><code>-type</code></td>
<td>Type of property to create; valid values are: string, int, long, double, bool, enum, file Default: string</td>

<td>Object type to create property for; valid values are: design, net, cell, pin, port, pblock, interface, fileset</td>
</tr>
</tbody>
</table>
Categories
PropertyAndParameter

Description

Creates a new property of the type specified with the user-defined name for the specified class of objects. The property that is created can be assigned to an object of the specified class with the set_property command, but is not automatically associated with all objects of that class.

The report_property -all command will not report the newly created property for an object of the specified class until the property has been assigned to that object.

Arguments

description - (Optional) Provide a description of the property being created. The description will be returned by the HSM help system when the property is queried.

type - (Optional) The type of property to create. Allowed property types include:

• string - Allows the new property to be defined with string values. This is the default value when -type is not specified.

• int - Allows the new property to be defined with short four-byte signed integer values with a range of -2,147,483,648 to 2,147,483,647. If a floating point value is specified for an int property type, the HSM tool will return an error.

• long - Specifies signed 64-bit integers with value range of -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807. If a floating point value is specified for a long property type, the tool will return an error.

• double - Allows the new property value to be defined with a floating point number.

• bool - Allows the new property to be defined as a boolean with a true (1, or yes) or false (0, or no) value.

• enum - An enumerated data type, with the valid enumerated values specified by the -enum_values option.

• string_list - A Tcl list of string values.

• int_list - A Tcl list of integer values.

• double_list - A Tcl list of floating point values.

-enum_values<args> - (Optional) A list of enumerated values that the property can have. The list must be enclosed in braces, {}, with values separated by spaces. This option can only be used with -type enum.

-default_value<args> - (Optional) The default value to assign to the property. This option can be used for string, int, bool, and enum type properties.
-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

*Note:* Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

*Note:* Message limits can be defined with the `set_msg_config` command.

<name> - (Required) The name of the property to be defined. The name is case sensitive.

<class> - (Required) The class of object to assign the new property to. All objects of the specified class will be assigned the newly defined property. Valid classes are: design, net, cell, pin, port, Pblock, interface, and files.

**Examples**

Create a property called PURPOSE for cell objects:

```bash
common::create_property PURPOSE cell
```

*Note:* Because the type was not specified, the value will default to "strings".

Create a pin property called COUNT which holds an Integer value:

```bash
common::create_property -type int COUNT pin
```

**See Also**

- `common::get_property`
- `common::list_property`
- `common::list_property_value`
- `common::report_property`
- `common::reset_property`
- `common::set_property`
**common::get_msg_config**

Returns the current message count, limit, or the message configuration rules previously defined by the `set_msg_config` command.

**Syntax**

```
```

**Returns**

Nothing

**Usage**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-id]</td>
<td>The message id to match. Should be used in conjunction with -limit or -count. Default: empty</td>
</tr>
<tr>
<td>[-severity]</td>
<td>The message severity to match. Should be used in conjunction with -limit or -count. Default: empty</td>
</tr>
<tr>
<td>[-rules]</td>
<td>Show a table displaying all message control rules for the current project.</td>
</tr>
<tr>
<td>[-limit]</td>
<td>Show the limit for the number of messages matching either -id or -severity that will be displayed</td>
</tr>
<tr>
<td>[-count]</td>
<td>Show the number of messages matching either -id or -severity that have been displayed</td>
</tr>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
</tbody>
</table>

**Categories**

Report
**common::get_param**

Get a parameter value.

**Syntax**

```
get_param [-quiet] [-verbose] <name>
```

**Returns**

Parameter value

**Usage**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>
<td>&lt;name&gt;</td>
<td>Parameter name</td>
</tr>
</tbody>
</table>

**Categories**

PropertyAndParameter

**Description**

Gets the currently defined value for a specified tool parameter. These parameters are user-definable configuration settings that control various behaviors within the tool. Refer to report_param for a description of what each parameter configures or controls.

**Arguments**

- `<name>` - (Required) The name of the parameter to get the value of. The list of user-definable parameters can be obtained with list_param. This command requires the full name of the desired parameter. It does not perform any pattern matching, and accepts only one parameter at a time.

- `-quiet` - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

  **Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- `-verbose` - (Optional) Temporarily override any message limits and return all messages from this command.
Note: Message limits can be defined with the `set_msg_config` command.

Examples

Get the current value of the messaging parameter used for enabling the description:

```
common::get_param messaging.enableDescription
```

See Also

- `common::list_param`
- `common::report_param`
- `common::reset_param`
- `common::set_param`
common::get_property

Get properties of object.

Syntax

```
get_property [-min] [-max] [-quiet] [-verbose] <name> <object>
```

Returns

Property value

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-min]</td>
<td>Return only the minimum value</td>
</tr>
<tr>
<td>[-max]</td>
<td>Return only the maximum value</td>
</tr>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>
<td>&lt;name&gt;</td>
<td>Name of property whose value is to be retrieved</td>
</tr>
<tr>
<td>&lt;object&gt;</td>
<td>Object to query for properties</td>
</tr>
</tbody>
</table>

Categories

Object, PropertyAndParameter

Description

Gets the current value of the named property from the specified object or objects. If multiple objects are specified, a list of values is returned.

If the property is not currently assigned to the object, or is assigned without a value, then the get_property command returns nothing, or the null string. If multiple objects are queried, the null string is added to the list of values returned.

This command returns a value, or list of values, or returns an error if it fails.

Arguments

- **-min** - (Optional) When multiple objects are specified, this option examines the values of the named property, and returns the smallest value from the list of objects. Numeric properties are sorted by value. All other properties are sorted as strings.
-max - (Optional) When multiple objects are specified, this option examines the values of the named property, and returns the largest value from the list of objects. Numeric properties are sorted by value. All other properties are sorted as strings.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.  
Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.  
Note: Message limits can be defined with the set_msg_config command.

<name> - (Required) The name of the property to be returned. The name is not case sensitive.

<object> - (Required) One or more objects to examine for the specified property.

Examples

Get the NAME property from the specified cell:

```
common::get_property NAME [lindex [get_cells] 0]
```

Get the BOARD property from the current hardware design:

```
common::get_property BOARD [current_hw_design]
```

Project
**common::list_param**

Get all parameter names.

**Syntax**

```
list_param [-quiet] [-verbose]
```

**Returns**

List

**Usage**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-quiet</code></td>
<td>Ignore command errors</td>
</tr>
<tr>
<td><code>-verbose</code></td>
<td>Suspend message limits during command execution</td>
</tr>
</tbody>
</table>

**Categories**

PropertyAndParameter

**Description**

Gets a list of user-definable configuration parameters. These parameters configure a variety of settings and behaviors of the tool. For more information on a specific parameter use the `report_param` command, which returns a description of the parameter as well as its current value.

**Arguments**

- `-quiet` - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

  **Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- `-verbose` - (Optional) Temporarily override any message limits and return all messages from this command.

  **Note:** Message limits can be defined with the `set_msg_config` command.
Examples

Get a list of all user-definable parameters:

```
common::list_param
```

Object, PropertyAndParameter

Description

Gets a list of all properties on a specified object or class.

Note: report_property returns a list of properties on an object or class of objects and also reports the property type and property value.

Arguments

- **-class <arg>** - (Optional) Return the properties of the specified class instead of a specific object. The class argument is case sensitive, and most class names are lower case.
  
  Note: -class cannot be used together with an <object>

- **-regexp** - (Optional) Specifies that the search <pattern> is written as a regular expression.
-quiet  (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose  (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

<object>  (Optional) A single object on which to report properties.

Note: If you specify multiple objects you will get an error.

<pattern>  (Optional) Match the available properties on the <object> or -class against the specified search pattern. The <pattern> applies to the property name, and only properties matching the specified pattern will be reported. The default pattern is the wildcard `*` which returns a list of all properties on the specified object.

Note: The search pattern is case sensitive, and most properties are UPPER case

Examples

The following example returns all properties of the specified CELL object:

```
common::list_property [get_cells microblaze_0]
```

See Also

- common::set_property
common::list_property_value

List legal property values of object.

Syntax

```
list_property_value [-default] [-class <arg>] [-quiet] [-verbose] <name>
[<object>]
```

Returns

List of property values

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-default]</td>
<td>Show only the default value.</td>
</tr>
<tr>
<td>[-class]</td>
<td>Object type to query for legal property values. Ignored if object is specified.</td>
</tr>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>
<td>&lt;name&gt;</td>
<td>Name of property whose legal values is to be retrieved</td>
</tr>
<tr>
<td>[&lt;object&gt;]</td>
<td>Object to query for legal properties values</td>
</tr>
</tbody>

</tr>
</tbody>
</table>

Categories

PropertyAndParameter, Report

Description

Gets a list of all user-definable parameters, the current value, and a description of what the parameter configures or controls.

Arguments

- **-file <arg>** - (Optional) Write the report into the specified file. The specified file will be overwritten if one already exists, unless -append is also specified.

  **Note:** If the path is not specified as part of the file name, the file will be written into the current working directory, or the directory from which the tool was launched.
<-append> - (Optional) Append the output of the command to the specified file rather than overwriting it.

*Note:* The -append option can only be used with the -file option.

<-return_string> - (Optional) Directs the output to a Tcl string rather than to the standard output. The Tcl string can be captured by a variable definition and parsed or otherwise processed.

*Note:* This argument cannot be used with the -file option.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

*Note:* Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

*Note:* Message limits can be defined with the set_msg_config command.

<pattern> (Optional) Match parameters against the specified pattern. The default pattern is the wildcard `*` which gets all user-definable parameters.

**Examples**

The following example returns the name, value, and description of all user-definable parameters:

```tcl
common::report_param
```

The following example returns the name, value, and description of user-definable parameters that match the specified search pattern:

```tcl
common::report_param *coll*
```

**See Also**

<td>[&lt;pattern&gt;]</td>
<td>Pattern to match properties against Default: *</td>
</tr>
</tbody>
</table>

**Categories**

Object, PropertyAndParameter, Report

**Description**

Gets the property name, property type, and property value for all of the properties on a specified object, or class of objects.

**Note:** list_property also returns a list of all properties on an object, but does not include the property type or value.
You can specify objects for `report_property` using the `get_*` series of commands to get a specific object. You can use the `lindex` command to return a specific object from a list of objects:

```
report_property [lindex [get_cells] 0]
```

However, if you are looking for the properties on a class of objects, you should use the `-class` option instead of an actual object.

This command returns a report of properties on the object, or returns an error if it fails.

**Arguments**

`<-all>` - (Optional) Return all of the properties for an object, even if the property value is not currently defined.

`-class<arg>` - (Optional) Return the properties of the specified class instead of a specific object. The class argument is case sensitive, and most class names are lower case.

*Note:* `-class` cannot be used together with an `<object>`

`<-return_string>` - (Optional) Directs the output to a Tcl string. The Tcl string can be captured by a variable definition and parsed or otherwise processed.

`-file<arg>` - (Optional) Write the report into the specified file. The specified file will be overwritten if one already exists, unless `-append` is also specified.

*Note:* If the path is not specified as part of the file name, the file will be written into the current working directory, or the directory from which the tool was launched.

`-append` - (Optional) Append the output of the command to the specified file rather than overwriting it.

*Note:* The `-append` option can only be used with the `-file` option

`-regexp` - (Optional) Specifies that the search `<pattern>` is written as a regular expression.

`-quiet` - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

*Note:* Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

`-verbose` - (Optional) Temporarily override any message limits and return all messages from this command.

*Note:* Message limits can be defined with the `set_msg_config` command.

`<object>` - (Optional) A single object on which to report properties.

*Note:* If you specify multiple objects you will get an error.
<pattern> - (Optional) Match the available properties on the <object> or -class against the specified search pattern. The <pattern> applies to the property name, and only properties matching the specified pattern will be reported. The default pattern is the wildcard `*` which returns a list of all properties on the specified object.

**Note:** The search pattern is case sensitive, and most properties are UPPER case.

**Examples**

The following example returns all properties of the specified object:

```tcl
common::report_property -all [get_cells microblaze_0]
```

To determine which properties are available for the different design objects supported by the tool, you can use multiple report_property commands in sequence. The following example returns all properties of the specified current objects:

```tcl
common::report_property -all [current_hw_design]
common::report_property -all [current_sw_design]
```

**See Also**

PropertyAndParameter

**Description**

Restores a user-definable configuration parameter that has been changed with the set_param command to its default value.

You can use the report_param command to see which parameters are currently defined.

**Arguments**

- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.
  
  *Note:* Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.
  
  *Note:* Message limits can be defined with the `set_msg_config` command.
<name> - (Required) The name of a parameter to reset. You can only reset one parameter at a time.

**Examples**

The following example restores the tcl.statsThreshold parameter to its default value:

```
common::reset_param tcl.statsThreshold
```

**See Also**

- common::get_param
- common::list_param
- common::report_param
- common::set_param
common::reset_property

Reset property on object(s).

Syntax

```
reset_property [-quiet] [-verbose] <property_name> <objects>..
```

Returns

The value that was set if success, "" if failure

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>

<td>Name of property to reset</td>
</tr>
<tr>
<td>&lt;objects&gt;</td>
<td>Objects to set properties</td>
</tr>
</tbody>
</table>

Categories

Object, PropertyAndParameter

Description

Restores the specified property to its default value on the specified object or objects. If no default is defined for the property, the property is unassigned on the specified object.

Arguments

- `-quiet` - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.
  
  **Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- `-verbose` - (Optional) Temporarily override any message limits and return all messages from this command.
  
  **Note:** Message limits can be defined with the `set_msg_config` command.

  `<property_name>` - (Required) The name of the property to be reset.
<objects> - (Required) One or more objects on which the property will be restored to its default value.

Examples

The following example sets the archiver property on the specified processor, and then resets the property:

```tcl
common::set_property CONFIG.archiver armar [get_sw_processor]
```

```tcl
common::reset_property CONFIG.archiver armar [get_sw_processor]
```

common::set_msg_config

Configure how the Vivado tool will display and manage specific messages based on message ID, string, or severity.

Syntax

```tcl
```

Returns
Nothing

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-id]</td>
<td>A qualifier, apply the selected operation only to messages that match given message id. Example: <code>-id {Common 17-35}</code>. Default: match any id</td>
</tr>
<tr>
<td>[-string]</td>
<td>A qualifier, apply the selected operation only to messages that contain the given list of strings. Default: none</td>
</tr>
<tr>
<td>[-severity]</td>
<td>A qualifier, apply the selected operation only to messages at the given severity level. Example: <code>-severity INFO</code> Default: match any severity</td>
</tr>
<tr>
<td>[-limit]</td>
<td>for the messages that match the qualifiers, limit the number of messages displayed to the given integer value. Can only be used in conjunction with one of -id or -severity.</td>
</tr>
<tr>
<td>[-new_severity]</td>
<td>for the messages that match the qualifiers, change the severity to the given value for the current project</td>
</tr>
<tr>
<td>[-suppress]</td>
<td>for the messages that match the qualifiers, suppress (do not display) any messages for the current project</td>
</tr>
<tr>
<td>[-regexp]</td>
<td>The values used for -string are full regular expressions</td>
</tr>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>

*PropertyAndParameter*

**Description**

Sets the value of a user-definable configuration parameter. These parameters configure and control various behaviors of the tool. Refer to report_param for a description of currently defined parameters.

You can use the reset_param command to restore any parameter that has been modified back to its default setting.

*Note:* Setting a specified parameter value to -1 will disable the feature

**Arguments**

- `<name>` - (Required) The name of the parameter to set the value of. You can only set the value of one parameter at a time.
- `<value>` - (Required) The value to set the specified parameter to.
- `-quiet` - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.
**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

**-verbose** *(Optional)* Temporarily override any message limits and return all messages from this command.

**Note:** Message limits can be defined with the `set_msg_config` command.

**Examples**

```
common::set_param messaging.defaultLimit 1000
```

**See Also**

- `common::get_param`
- `common::list_param`
- `common::report_param`
- `common::reset_param`
common::set_property

Set property on object(s).

Syntax

```
set_property [-dict <args>] [-quiet] [-verbose] <name> <value> <objects>..
```

Returns

Nothing

Usage

<table>
<thead>
<tr>
<th>Name</th>

<td>Value of property to set. Not valid with -dict option</td>
</tr>
<tr>
<td>&lt;objects&gt;</td>
<td>Objects to set properties on</td>
</tr>
</tbody>
</table>

Categories

Object, PropertyAndParameter

Description

Assigns the defined property <name> and <value> to the specified <objects>.

This command can be used to define any property on an object in the design. Each object has a set of predefined properties that have expected values, or a range of values. The set_property command can be used to define the values for these properties. To determine the defined set of properties on an object, use report_property, list_property, or list_property_values.

You can also define custom properties for an object by specifying a unique <name> and <value> pair for the object. If an object has custom properties, these will also be reported by the report_property and list_property commands.

This command returns nothing if successful, and an error if it fails.

Note: You can use the get_property command to validate any properties that have been set on an object.
Arguments

- **-dict** - (Optional) Use this option to specify multiple properties (<name> <value> pairs) on an object with a single set_property command. Multiple <name> <value> pairs must be enclosed in braces, {}, or quotes, "".

```
-dict "name1 value1 name2 value2 ... nameN valueN"
```

- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

*Note:* Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.

*Note:* Message limits can be defined with the `set_msg_config` command.

- **<name>** - (Required) Specifies the name of the property to be assigned to the object or objects. The <name> argument is case sensitive and should be specified appropriately.

- **<value>** - (Required) Specifies the value to assign to the <name> on the specified object or objects. The value is checked against the property type to ensure that the value is valid. If the value is not appropriate for the property an error will be returned.

*Note:* In some cases the value of a property may include special characters, such as the dash character (`-`), which can cause the tool to interpret the value as a new argument to the command. In this case, you must use the explicit arguments (-name, -value, -objects) instead of the implied positional arguments (name, value, objects) as described here. This is shown in the Examples section below.

- **<objects>** - (Required) One or more objects to assign the property to.

Examples

Create a user-defined boolean property, TRUTH, for cell objects, and set the property on a cell:

```
common::create_property -type bool truth cell
common::set_property truth false [lindex [get_cells] 1]
```

The following example sets the compiler and archiver property value for the specified software processor:

```
common::set_property CONFIG.archiver armar [get_sw_processor]
common::set_property CONFIG.compiler armcc [get_sw_processor]
```

- hsi::get_cells
- common::get_property
- common::list_property
- common::list_property_value
- common::report_property
- common::reset_property
common::unregister_proc

Unregister a previously registered Tcl proc.

Syntax

```
unregister_proc [-quiet] [-verbose] <tasknm>
```

Returns

Nothing

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>
<td>&lt;tasknm&gt;</td>
<td>Name of Tcl task to unregister. The task must be wrapping a proc.</td>
</tr>
</tbody>
</table>

Categories

Tools
common::version

Returns the build for hsi and the build date.

Syntax

version [-short] [-quiet] [-verbose]

Returns

Hsi version

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-short]</td>
<td>Return only the numeric version number</td>
</tr>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
</tbody>
</table>

Categories

Report
hsi::add_library

Add software library to software design.

Syntax

```
add_library [-sw <arg>] [-quiet] [-verbose] <name> [<version>]
```

Returns

The Software Library object. Returns nothing if the command fails

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-sw]</td>
<td>Software design name</td>
</tr>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>
<td>&lt;name&gt;</td>
<td>Software library name</td>
</tr>
<tr>
<td>[&lt;version&gt;]</td>
<td>Version of software Library</td>
</tr>
</tbody>
</table>

Categories

Software

Description

Adds library to the active software design. The software design must previously have been created using the create_sw_design command. This command returns a message with the name of the library, or returns an error if the command fails.

Arguments

`<-sw>` - (Optional) Name of the software design to which library to the added.

`-quiet` - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

*Note:* Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

`-verbose` - (Optional) Temporarily override any message limits and return all messages from this command.
**Note:** Message limits can be defined with the `set_msg_config` command.

`<name>` - Name of the library.

`<version>` - (Optional) Version of the library name. Version less library will be picked if version is not specified.

**Examples**

The following adds the specified Library to the current software design:

```
hsi::add_library xilffs
```

adds version of the library

```
hsi::add_library xilrsa 1.0
```

**See Also**

- `hsi::current_sw_design`
hsi::close_hw_design

Close a hardware design.

Syntax

close_hw_design [-quiet] [-verbose] <name>

Returns

Returns nothing, error message if failed

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>
<td>&lt;name&gt;</td>
<td>Name of design to close</td>
</tr>
</tbody>
</table>

Categories

Hardware

Description

Closes the hardware design in the HSM active session. Design modification is not allowed in the current release, otherwise it will prompt to save the design prior to closing.

Arguments

- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

  *Note:* Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.

  *Note:* Message limits can be defined with the `set_msg_config` command.

- **<name>** - The name of the hardware design object to close.
Examples

Close the current hardware design object:

hsi::close_hw_design [current_hw_design]

Close the specified hardware design object:

hsi::close_hw_design design_1_imp

See Also

- hsi::current_hw_design
- hsi::get_hw_designs
- hsi::open_hw_design
hsi::close_sw_design

Close a software design.

Syntax

```
close_sw_design [-quiet] [-verbose] <name>..
```

Returns

Returns nothing, error message if failed

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>
<td>&lt;name&gt;</td>
<td>Name of design to close</td>
</tr>
</tbody>
</table>

Categories

Software

Description

Closes the specified software design in the current Hardware Software Interface session.

**IMPORTANT!: If the design has been modified, you will not be prompted to save the design prior to closing. In the current release the persistence option is not available.**

Arguments

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

*Note:* Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

*Note:* Message limits can be defined with the `set_msg_config` command.
<name> - The name of the software design object to close.

Examples

Close the current software design in the current session:

hsi::close_sw_design [current_sw_design]

hsi::close_sw_design

Close the specified software design in the current session:

hsi::close_sw_design [current_sw_design]

See Also

- hsi::open_sw_design
hsi::create_comp_param

Add Parameter.

Syntax

create_comp_param [-quiet] [-verbose] <name> <value> <objects>

Returns

Parameter object. Returns nothing if the command fails

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>

<td>Parameter name</td>
</tr>
<tr>
<td>&lt;value&gt;</td>
<td>Parameter value</td>
</tr>
<tr>
<td>&lt;objects&gt;</td>
<td>List of Nodes</td>
</tr>
</tbody>
</table>

Categories

Software

Description

Create a new param to list of nodes (driver/os/proc/node).

If successful, this command returns the name of the param created. Otherwise it returns an error.

Arguments

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.
<name> - The name of the param to create.

<value> - The value of the param to create. Default type of param is string.

<objects> - List of nodes to which new param is created.

**Examples**

The following example creates a new param called p1 to specified driver:

```
hsi::create_comp_param p1 [get_drivers ps7_uart_1]
```

The following example creates a new param called p2 to all drivers.

```
hsi::create_comp_param p2 [get_drivers]
```

**See Also**

- `hsi::create_node`
- `hsi::create_sw_design`
hsi::create_dt_node

Create a DT Node.

Syntax

```
create_dt_node -name <arg> [-unit_addr <arg>] [-label <arg>] [-objects <args>] [-quiet] [-verbose]
```

Returns

DT Node object. Returns nothing if the command fails

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-name</td>
<td>child DT node name</td>
</tr>
<tr>
<td>[-unit_addr]</td>
<td>unit address of node</td>
</tr>
<tr>
<td>[-label]</td>
<td>label of node</td>
</tr>
<tr>
<td>[-objects]</td>
<td>List of nodes</td>
</tr>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
</tbody>
</table>

Categories

DeviceTree

Description

Create a new DT node and add to the current DT tree.

If successful, this command returns the name of the DT node created where name is represented as `<node_label>+<node_name>+@<unit_address>`. Otherwise it returns an error.

Arguments

- `-name` - The name of the node to be created.
- `-label` - The label of the node to represent in generated dtsi file.
- `--unit_addr` - The unit address of the node to represent in generated dtsi file.
-objects - The list of node objects where the newly created node will be a child to all specified nodes.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

Examples

Create a new DT node amba with label axi_interconnect and unit_addr 0x000 in the current DT tree:

hsi::create_dt_node -name amba -label axi_interconnect -unit_addr 0x000
hsi::create_dt_node -name amba -label axi_interconnect -unit_addr 0x000 -objects [get_dt_nodes -of_objects [current_dt_tree]]

See Also

- hsi::get_dt_nodes

hsi::create_dt_tree

Create a DT tree.

Syntax

```
cREATE_DT_TREE -dts_file <arg> [ -dts_version <arg> ] [ -quiet ] [ -verbose ]
```

Returns

Tree object. Returns nothing if the command fails

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dts_file</td>
<td>dts file name</td>
</tr>
<tr>
<td>[-dts_version]</td>
<td>dts version</td>
</tr>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
</tbody>
</table>

Categories

DeviceTree

Description

Create a new DT tree add to the current HSI session.

If successful, this command returns the name of the DT tree created. Otherwise it returns an error.

Arguments

- **-dts_file** - The DT tree name or file name targeted for the output DTSI file.

- **-dts_version** - The DTS version of the DTSI file.

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.

*Note*: Message limits can be defined with the `set_msg_config` command.
Examples

Create a new DT tree pl.dtsi and add the tree to the current session:

```bash
hsi::create_dt_tree -dts_file pl.dtsi -dts_version /dts-v1/
```

```bash
hsi::create_dt_tree -dts_file system.dts -dts_version /dts-v3/ -header "include pl.dtsi, include ps.dtsi"
```

```bash
hsi::create_dt_tree -dts_file ps.dtsi -dts_version /dts-v3/ -header "PS system info"
```

See Also

- `hsi::current_dt_tree`
- `hsi::get_dt_trees`
hsi::create_node

Add Node.

Syntax

create_node [-quiet] [-verbose] <name> <objects>

Returns

Node object. Returns nothing if the command fails

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>

<tr>
<td>&lt;name&gt;</td>
<td>child node name</td>
</tr>
<tr>
<td>&lt;objects&gt;</td>
<td>List of nodes</td>
</tr>
</tbody>
</table>

Categories

Software

Description

Create a new node to list of existing nodes (driver/os/prco/node).

If successful, this command returns the name of the node created. Otherwise it returns an error.

Arguments

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

$name$ - The name of the node to create.
<objects> - List of nodes to which new node is created.

Examples
The following example creates a new node called n1 to the specified driver:

```tcl
hsi::create_node n1 [get_drivers ps?_uart_1]
```

The following example creates a new node called n2 to all drivers.

```tcl
hsi::create_node n2 [get_drivers]
```

See Also

</tr>
<tr>
<td>&lt;name&gt;</td>
<td>Software design name</td>
</tr>
</tbody>
</table>

**Categories**

Software

**Description**

Create a new software design module to add to the current session.

If successful, this command returns the name of the software design created. Otherwise it returns an error.

**Arguments**

- **-proc** - The processor instance name targeted for the software design.
- **-app** - The template application name.
- **-os** - (Optional) The OS name targeted for the software design. Default value is standalone.
-os_ver - (Optional) The OS version targeted for the software design. Default value is the latest OS version.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

$name$ - The name of the software design module to create.

Examples

Create a new software design module called sw_design_1 and add the module to the current session:

hsi::create_sw_design sw_design_1 -proc microblaze_0 -os xilkernel

hsi::create_sw_design sw_design_1 -proc microblaze_0 -os xilkernel -os_ver 6.0

hsi::create_sw_design sw_design_1 -proc ps7_cortexa9_0

DeviceTree

**Description**

Defines the current DT tree for use with the Hardware Software Interface, or returns the name of the current DT tree in the active session.

The current DT tree is the target of the Hardware Software Interface - DeviceTree Tcl commands.

You can use the `get_dt_trees` command to get a list of created DT trees in the active session.

**Arguments**

- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

  **Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.

  **Note:** Message limits can be defined with the `set_msg_config` command.
<dt_tree> - (Optional) The name of a DT tree to set as the current DT tree in the session. If a dt_tree is not specified, the command returns the current DT tree of the active session.

**Examples**

Get the current DT tree object:

```tcl
hsi::current_dt_tree
```

OR

Set the specified dt_tree as the current session:

```tcl
hsi::current_dt_tree pl.dtsi
```

**See Also**

- `hsi::create_dt_tree`
- `hsi::get_dt_trees`
hsicurrent_hw_design

Set or get current hardware design.

Syntax

current_hw_design [-quiet] [-verbose] [<design>]

Returns

Current hardware design object, "" if failed

Usage

<table>

Hardware

Description

Defines the current hardware design for use with the Hardware Software Interface, or returns the name of the current design in the active project.

The current hardware design is the target of the Hardware Software Interface hardware Tcl commands.

You can use the get_hw_designs command to get a list of open hardware designs in the active project.

Arguments

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.
Note: Message limits can be defined with the `set_msg_config` command.

<design> - (Optional) The name of a hardware design to set as the current design in the session. If a design is not specified, the command returns the current hardware design of the active session.

**Examples**

Get the current hardware design object:

```tcl
hsi::current_hw_design
```

OR

Set the specified hardware design object as the current design:

```tcl
hsi::current_hw_design hw_design_1
```

**See Also**

- `hsi::close_hw_design`
- `hsi::get_hw_designs`
- `hsi::open_hw_design`
hsi::current_hw_instance

Set or reset current hardware instance.

Syntax

hsi::current_hw_instance [ -quiet ] [ -verbose ] [ <instance> ]

Returns

Current cell instance object, "" if failed

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ -quiet ]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[ -verbose ]</td>
<td>Suspend message limits during command execution</td>

<tr>
<td>[ &lt;instance&gt; ]</td>
<td>hardware cell instance to be set</td>
</tr>
</tbody>
</table>

Categories

Hardware

Description

Sets or resets the current hardware instance to the given hierarchial instance, for scoping the hardware data access commands in a hierarchial design. Default is top design.

Arguments

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.

  **Note**: Message limits can be defined with the `set_msg_config` command.

- **<instance>** - (Optional) Hardware cell instance (hierarchial instance) to be set.
Examples

The following example sets the current hardware instance to axi_ethernet_0:

```tcl
hsi::current_hw_instance [get_cells axi_ethernet_0]
hsi::get_cells
```

Returns the hardware cell instances inside current hierarchical instance `axi_ethernet_0`.

Software

Description

Sets the current software design for use with the Hardware Software Interface, or returns the name of the current design in the active project.

The current software design is the target of the Hardware Software Interface software Tcl commands.

You can use the get_sw_designs command to get a list of open software designs in the active project.

Arguments

- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.
  **Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.
Note: Message limits can be defined with the `set_msg_config` command.

<design> - (Optional) The name of a software design to set as the current design in the Hardware Software Interface. If a design is not specified, the command returns the current software design of the active project.

Examples

Get the current software design object:

```tcl
hsi::current_sw_design
```

OR

Set the specified software design object as the current design:

```tcl
hsi::current_sw_design sw_design_1
```

hsi::delete_objs

Delete specified objects.

Syntax

```
delete_objs [-quiet] [-verbose] <objects>..
```

Returns

Pass if successful in deleting objects

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>
<td>&lt;objects&gt;</td>
<td>The objects to be deleted</td>
</tr>
</tbody>
</table>

Categories

Software

Description

Delete specified objects from the current software design.

Objects must be passed directly to the delete_objs command, and not simply referenced by the object name.

This command returns nothing if it is successful, and returns an error if it fails.

Arguments

- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.
  
  **Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.
  
  **Note:** Message limits can be defined with the `set_msg_config` command.
<objects> - A list of objects to delete from the current software design.

**Examples**

The following example deletes the specified objects from the current software design:

```tcl
hsi::delete_objs [get_libs xilffs] [get_drivers gpio]
```
hsi::generate_app

Generates Template Application.

Syntax

Returns
Returns nothing

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-dir]</td>
<td>Output directory where App needs to be generated</td>
</tr>
<tr>
<td>[-hw]</td>

<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>
</tr>
</tbody>
</table>

Categories

Software

Description

Generates a template application for a processor on an operating system

If successful, this command returns nothing. Otherwise it returns an error.
Arguments

- **-dir** - (Optional) The output where the application needs to be generated.
- **-hw** - (Optional) Hardware design name.
- **-hw_xml** - (Optional) XML file path of the hw design.
- **-sw** - (Optional) Software design name.
- **-proc** - Instance Name of the Processor to which App needs to be generated.
- **-os** - (Optional) Name of Operating System for App.
- **-app** - Name of the application.
- **-lapp** - (Optional) List all the Applications in Repositories.
- **-sapp** - (Optional) List all the Supported Applications for Hardware and Software Designs.
- **-compile** - (Optional) Compile the generated source files.
- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution. 
  
  **Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.
- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.
  
  **Note:** Message limits can be defined with the `set_msg_config` command.

Examples

List all applications in the repositories:

```sh
hsi::generate_app -lapp
```

The following example gets a list of all supported applications for processor ps7_cortexa9_0 and standalone operating system:

```sh
hsi::generate_app -sapp -proc ps7_cortexa9_0
```
The following example generates a hello_world application for processor microblaze_0 for xilkernel OS:

hsi::generate_app -app hello_world -proc microblaze_0 -os xilkernel

Software

Description

Generates a template application for a processor on an operating system

If successful, this command returns nothing. Otherwise it returns an error.
Arguments

- **-dir** - (Optional) Output directory where BSP needs to be generated.
- **-hw** - (Optional) Hardware design name.
- **-hw_xml** - (Optional) XML file path of the hw design.
- **-sw** - (Optional) Software design name.
- **-sw_mss** - (Optional) Software Design MSS File Path.
- **-proc** - Instance Name of the Processor to which BSP needs to be generated.
- **-os** - (Optional) Name of Operating System for BSP.
- **-os_ver** - (Optional) Version of Operating System for BSP.
- **-compile** - (Optional) Compile the generated source files.
- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.
  
  **Note**: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.
- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.
  
  **Note**: Message limits can be defined with the `set_msg_config` command.

Examples

generates a BSP for the processor ps7_cortexa9_0:

```
hsi::generate_bsp -proc ps7_cortexa9_0
```

The following example generates BSP for the processor ps7_cortexa9_0 for a MSS file sw_app.mss:

```
hsi::generate_bsp -sw_mss sw_app.mss
```

Software

Description

Arrays are defined in MDD/MLDs. It contains any number of PARAMs and PROPERTYs which describes size, description of array and default values of elements in array.

Arguments

- `-regexp` (Optional) Specifies that the search `<patterns>` are written as regular expressions. Both search `<patterns>` and `-filter` expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command `regexp` is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.
-filter <args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

**Note:** The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (==), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For array objects, "NAME", and "other config parameters" are some of the properties that can be used to filter results.

-of_objects <arg> - (Optional) Get the arrays that are available in OS, Drivers, Libraries, Processor, and Core, as returned by the get_os, get_drivers, get_libs, get_sw_processor, or get_sw_cores commands.

**Note:** The -of_objects option requires objects to be specified using one of the the get_* commands such as get_os or get_libs, rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

**Note:** Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match arrays against the specified patterns. The default pattern is the wildcard "*" which gets a list of all arrays. More than one pattern can be specified to find multiple arrays based on different search criteria.

**Note:** You must enclose multiple search patterns in braces {} to present the list as a single element.
Examples

The following example gets a list of arrays present in all software cores(drivers/libs/os)

hsi::get_arrays

The following example gets a list of all arrays matching the name "mem_table"

hsi::get_arrays mem_table

The following example gets a list of arrays present in OS of current software design.

hsi::get_arrays -of_objects [get_os]

See Also

- hsi::get_sw_interfaces
hsi::get_cells

Get a list of cells.

Syntax

```
get_cells [-regexp] [-filter <arg>] [-hierarchical] [-of_objects <args>]
[-quiet] [-verbose] [<patterns>...]
```

Returns

Cell objects. Returns nothing if the command fails

Usage

<table>
<thead>
<tr>
<th>Name</th>

Hardware

Description

Gets a list of IP instance objects in the current design that match a specified search pattern. The default command returns a list of all IP instances in the design.

**Note:** To improve memory and performance, the get_ * commands return a container list of a single type of objects (e.g. cells, nets, or ports). You can add new objects to the list (using lappend for instance), but you can only add the same type of object that is currently in the list. Adding a different type of object or string to the list is not permitted and will result in a Tcl error.
Arguments

- regexp (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.

- filter <args> (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "***" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

Note: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "***" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For cell objects, "IP_TYPE", and "IP_NAME" are some of the properties you can use to filter results. The following gets cells with an IP_TYPE of "PROCESSOR" and with names containing "ps7":

```tcl
get_cells * -filter {IP_TYPE == PROCESSOR && NAME != "*ps7*"}
```

- hierarchical (Optional) Get cells from all levels of hierarchical cells.

- of_objects <arg> (Optional) Get the cells connected to the specified pins, timing paths, nets, bels, clock regions, sites, or DRC violation objects.

- quiet (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.
-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match cells against the specified patterns. The default pattern is the wildcard `*` which gets a list of all cells in the project. More than one pattern can be specified to find multiple cells based on different search criteria.

Note: You must enclose multiple search patterns in braces, {}, or quotes, "", to present the list as a single element.

Examples

The following example returns list of processor instances:

```tcl
hsi::get_cells -filter { IP_TYPE == "PROCESSOR" }
```

This example gets a list of properties and property values attached to the second object of the list returned by get_cells:

```tcl
common::report_property [lindex [get_cells] 1]
```

Note: If there are no cells matching the pattern you will get a warning.

Software

Description

Get a list of params in drivers/os/nodes in the current software design.

Arguments

- regexp (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "***" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

Note: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "***" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (==), "not-equal" (!=), "match" (~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

The following gets params that match NAME and VALUE within their name:

```
get_comp_params -filter {NAME == clock_names && VALUE == 'ref_clk aper_clk'}
```

-of_objects<arg> - (Optional) Get 'node' objects of these types: 'sw_driver', 'sw_os', 'sw_proc', 'sw_node'.

Note: The -of_objects option requires objects to be specified using the get_* commands, such as get_nodes, rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match software design cells against the specified patterns. The default pattern is the wildcard "*" which gets a list of all cells in the current IP subsystem design. More than one pattern can be specified to find multiple cells based on different search criteria.

Note: You must enclose multiple search patterns in braces, {}, to present the list as a single element.
Examples

The following example gets a list of params that include the specified driver in the software design:

hsi::get_comp_params -of_objects [get_drivers ps7_uart_0]

The following example gets a list of all params of OS:

hsi::get_comp_params -of_objects [get_os]

See Also

**Categories**

Software

**Description**

Get a list of driver instances in the current software design. Each instance is mapping to the IP instances in the loaded hardware design. Generic driver is assigned for the IPs which does not have drivers.

**Arguments**

*regexp* - (Optional) Specifies that the search `<patterns>` are written as regular expressions. Both search `<patterns>` and `-filter` expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.
Note: The Tcl built-in command `regexp` is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.

-`filter <args>` - (Optional) Filter the results list with the specified expression. The `filter` argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the `report_property` or `list_property` commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard `*` character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

Note: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the `*` wildcard character, this will match a property with a defined value of `""`.

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and => can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

NAME and HW_INSTANCE are some of the properties you can use to filter results for drivers. The following gets drivers named gpio with a HW_INSTANCE of axi_gpio_0:

```
get_drivers * -filter {NAME==gpio && HW_INSTANCE == axi_gpio_0}
```

-`of_objects <arg>` - (Optional) Get 'driver' objects of these types: 'sw_design'.

-`-quiet` - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-`-verbose` - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the `set_msg_config` command.

-`patterns` - (Optional) Match software design cells against the specified patterns. The default pattern is the wildcard `*` which gets a list of all cells in the current IP subsystem design. More than one pattern can be specified to find multiple cells based on different search criteria.

Note: You must enclose multiple search patterns in braces {} to present the list as a single criteria.
Examples

The following example gets a list of drivers that include the specified Software design:

hsi::get_drivers

The following example gets a list of all driver instances of gpio driver:

hsi::get_drivers * -filter [NAME==gpio]

See Also

- hsi::get_libs
- hsi::get_os

DeviceTree

Description

Gets a list of DT nodes created under a DT tree in the current HSI session that match a specified search pattern. The default command gets a list of all root DT nodes in the current DT tree.

Arguments

- **-of_objects <arg>** - (Optional) Gets all nodes of DTSNode and DTSTree

*Note:* The -of_objects option requires objects to be specified using one of the get_* commands such as get_dt_nodes or get_dt_trees rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>
-regexp - (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.

-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match nodes against the specified patterns. The default pattern is the wildcard `*` which gets a list of all root nodes in the current DT tree. More than one pattern can be specified to find multiple nodes based on different search criteria.

Note: You must enclose multiple search patterns in braces, {}, or quotes, "", to present the list as a single element.

Examples

The following example gets a list of root nodes attached to the specified DT tree:

```
hsi::get_dt_nodes -of_objects [lindex [get_dt_trees] 1]
```

Note: If there are no nodes matching the pattern, the tool will return empty.

The following example gets a list of all nodes in the current DT tree:

```
hsi::get_dt_nodes -hier
```

Note: If there are no nodes matching the pattern, the tool will return empty.
The following example gets a list of nodes created under a root node:

```
hsi::get_dt_nodes -of_objects [current_dt_tree]
```

Note: If there are no nodes matching the pattern, the tool will return empty.

See Also

- `hsi::current_dt_tree`

DeviceTree

Description

Gets a list of DT trees created in the current HSI session that match a specified search pattern. The default command gets a list of all open DT trees in the HSI session.

Arguments

- `regexp` (Optional) Specifies that the search `<patterns>` are written as regular expressions. Both search `<patterns>` and `-filter` expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command `regexp` is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

Note: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For the "DT tree" object you can use the "DTS_FILE_NAME" property to filter results. The following gets dt trees that do NOT contain the "pl.dtsi" substring within their name:

```
get_dt_trees * -filter {NAME !~ '*pl.dtsi*'}
```

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match DT trees against the specified patterns. The default pattern is the wildcard "*" which gets all DT trees. More than one pattern can be specified to find multiple trees based on different search criteria.

Examples

Get all created DT trees in the current session:

```
hsi::get_dt_trees
```

See Also

**Categories**

Software

**Description**

Get a list of fields of a register. By default, the command returns the fields of all registers, of all the cells.

**Arguments**

- `-regexp` *(Optional)* Specifies that the search `<patterns>` are written as regular expressions. Both search `<patterns>` and `-filter` expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See [http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm](http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm) for help with regular expression syntax.

**Note:** The Tcl built-in command `regexp` is not anchored, and works as a standard Tcl command. For more information refer to [http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm](http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm).
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "**" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

**Note:** The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "**" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (==), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For array objects, "NAME", and "other config parameters" are some of the properties that can be used to filter results.

-of_objects<arg> - (Optional) Get 'field' objects of these types: 'register'.

**Note:** The -of_objects option requires objects to be specified using the get_registers command, rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

**Note:** Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match field names against the specified patterns. The default pattern is the wildcard "*" which gets a list of all fields. More than one pattern can be specified to find multiple fields based on different search criteria.

**Note:** You must enclose multiple search patterns in braces {} to present the list as a single element.

**Examples**

The following example gets a list of fields present in all registers of all the software driver cores:

```hs
hsi::get_fields
```
hsi::get_hw_designs

Get a list of hardware designs opened.

Syntax

```tcl
get_hw_designs [-regexp] [-filter <arg>] [-quiet] [-verbose] [<patterns>...]
```

Returns

Hardware design objects. Returns nothing if the command fails

Usage

<table>

Categories

Hardware

Description

Gets a list of hardware designs open in the current HSM session that match a specified search pattern. The default command gets a list of all open hardware designs in the session.

Arguments

- **-regexp** - (Optional) Specifies that the search `<patterns>` are written as regular expressions. Both search `<patterns>` and `-filter` expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See [http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm](http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm) for help with regular expression syntax.

**Note:** The Tcl built-in command `regexp` is not anchored, and works as a standard Tcl command. For more information refer to [http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm](http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm).
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

**Note:** The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the ":" wildcard character, this will match a property with a defined value of ""

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For the "Hardware design" object you can use the "NAME" property to filter results. The following gets hardware designs that do NOT contain the "design" substring within their name:

```tcl
get_hw_designs * -filter {NAME !~ "*design*"}
```

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

**Note:** Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match designs against the specified patterns. The default pattern is the wildcard "*" which gets all hardware designs. More than one pattern can be specified to find multiple designs based on different search criteria.

**Examples**

Get all open hardware designs in the current session:

```tcl
hsi::get_hw_designs
```

**See Also**

- [hsi::close_hw_design](#)
- [hsi::current_hw_design](#)
• hsi::open_hw_design
hsi::get_hw_files

Get a list of hardware design supporting files.

Syntax

```
hsi::get_hw_files [-regexp] [-filter <arg>] [-of_objects <args>] [-quiet] [-verbose] [<patterns>...]
```

Returns

Hardware design supporting file objects. Returns nothing if the command fails.

Hardware

Description

Gets a list of hardware handoff files in the current hardware session.

Arguments

- `-regexp` - (Optional) Specifies that the search `<patterns>` are written as regular expressions. Both search `<patterns>` and `-filter` expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command `regexp` is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

**Note:** The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "."

For string comparison, the specific operators that can be used in filter expressions are "equal" (==), "not-equal" (!=), "match" (~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For "file" objects you can use the "TYPE" property to filter results.

(of_objects<args> - (Optional) Get the files that are associated with the specified fileset objects. The default is to search all filesets. When -compile_order and -used_in are specified, the -of_objects switch will only accept a single fileset, or a single sub-design such as an IP core, Block Design, or DSP design. A sub-design is also known as a composite file.

**Note:** The -of_objects option requires objects to be specified using one of the get_* commands such as get_cells or get_pins rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>.

-q quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-v verbose - (Optional) Temporarily override any message limits and return all messages from this command.

**Note:** Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match files against the specified patterns. The default pattern is the wildcard "*" which gets all files in the project or of_objects. More than one pattern can be specified to find multiple files based on different search criteria.
Examples

The following example returns the bit files in the design that are used for programming FPGA:

hsi::get_hw_files -filter {TYPE == bit}
hsi::get_intf_nets

Get a list of interface Nets.

Syntax

Returns

Interface Net objects. Returns nothing if the command fails

Usage

<table>

Hardware

Description

Gets a list of interface nets in the current hardware design that match a specified search pattern. The default command gets a list of all interface nets in the subsystem design.
Arguments

-<regexp> - (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.

-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

Note: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of ".".

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For hardware design nets you can use the "NAME" property to filter results.

-hierarchical - (Optional) Get interface nets from all levels of hierarchical cells.

-boundary_type - (Optional) Used when source object is on a hierarchical block's pin. Valid values are 'upper', 'lower', or 'both'. If 'lower' boundary, searches from the lower level of hierarchy onwards. This option is only valid for connected_to relations.

-of_objects<args> - (Optional) Get a list of the nets connected to the specified IP Integrator subsystem cell, pin, or port objects.

Note: The -of_objects option requires objects to be specified using one of the get_* commands such as get_cells or get_pins rather than specifying objects by name. In addition, -of_objects cannot be used with a search pattern.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.
**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

`-verbose` - (Optional) Temporarily override any message limits and return all messages from this command.

**Note:** Message limits can be defined with the `set_msg_config` command.

`<patterns>` - (Optional) Match hardware design interface nets against the specified patterns. The default pattern is the wildcard `*` which returns a list of all interface nets in the current IP Integrator subsystem design. More than one pattern can be specified to find multiple nets based on different search criteria.

**Note:** You must enclose multiple search patterns in braces `{}` to present the list as a single element.

### Examples

The following example gets the interface net attached to the specified pin of an hardware design, and returns the net:

```tcl
hsi::get_intf_nets -of_objects [get_pins aclk]
```

**Note:** If there are no interface nets matching the pattern you will get a warning.

Hardware

Description

 Gets a list of pin objects in the current design that match a specified search pattern. The default command gets a list of all pins in the design.

Arguments

- regexp  (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.
Note: The Tcl built-in command *regexp* is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.

- **filter**<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

Note: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "."

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

"NAME" and "TYPE" are some of the properties you can use to filter results for interface pins. The following gets slave interface pins that do NOT contain the "S_AXI" substring within their name:

```
get_intf_pins * -filter {TYPE == SLAVE && NAME !~ "*S_AXI*"}
```

- **hierarchical** - (Optional) Get interface pins from all levels of hierarchical cells.

- **of_objects**<arg> - (Optional) Get the pins connected to the specified cell, clock, timing path, or net; or pins associated with specified DRC violation objects.

Note: The -of_objects option requires objects to be specified using one of the get_* commands such as get_cells or get_pins rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>

- **match_style** [sdc | ucf] - (Optional) Indicates that the search pattern matches UCF constraints or SDC constraints. The default is SDC.

- **quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **verbose** - (Optional) Temporarily override any message limits and return all messages from this command.
Note: Message limits can be defined with the `set_msg_config` command.

`<patterns>` - (Optional) Match pins against the specified patterns. The default pattern is the wildcard `*` which gets a list of all pins in the project. More than one pattern can be specified to find multiple pins based on different search criteria.

Note: You must enclose multiple search patterns in braces, [], or quotes, "", to present the list as a single element.

Examples

The following example gets a list of pins attached to the specified cell:

```
hsi::get_intf_pins -of_objects [lindex [get_cells] 1]
```

Note: If there are no pins matching the pattern, the tool will return a warning.

Hardware

Description

Gets a list of interface port objects in the current hardware subsystem design that match a specified search pattern. The default command gets a list of all interface ports in the subsystem design.

The external connections in an IP subsystem design are ports, or interface ports. The external connections in an IP Integrator cell or hierarchical module are pins and interface pins. Use the get_pins and get_intf_pins commands to select the pin objects.

Note: To improve memory and performance, the get_* commands return a container list of a single type of objects (e.g. cells, nets, pins, or ports). You can add new objects to the list (using lappend for instance), but you can only add the same type of object that is currently in the list. Adding a different type of object or string to the list is not permitted and will result in a Tcl error.
Arguments

-\textit{regexp} - (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -\textit{filter} expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See \url{http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm} for help with regular expression syntax.

\textbf{Note:} The Tcl built-in command \textit{regexp} is not anchored, and works as a standard Tcl command. For more information refer to \url{http://www.tcl.tk/man/tcl8.5/TclCmd/reg_exp.htm}.

-\textit{filter} <\textit{args}> - (Optional) Filter the results list with the specified expression. The -\textit{filter} argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the \texttt{report_property} or \texttt{list_property} commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

\textbf{Note:} The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and => can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For IP subsystem interface ports, "DIRECTION", and "NAME" are some of the properties you can use to filter results.

-\textit{of_objects} <\textit{arg}> - (Optional) Get the interface ports connected to the specified IP subsystem interface nets returned by \texttt{get_intf_nets}.

\textbf{Note:} The -of_objects option requires objects to be specified using the \texttt{get_*} commands, such as \texttt{get_cells} or \texttt{get_pins}, rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>.

-\textit{quiet} - (Optional) Execute the command quietly, returning no messages from the command. The command also returns \texttt{TCL\_OK} regardless of any errors encountered during execution.

\textbf{Note:} Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-\textit{verbose} - (Optional) Temporarily override any message limits and return all messages from this command.

\textbf{Note:} Message limits can be defined with the \texttt{set_msg_config} command.
<patterns> - (Optional) Match interface ports against the specified patterns. The default pattern is the wildcard `*` which gets a list of all interface ports in the subsystem design. More than one pattern can be specified to find multiple interface ports based on different search criteria.

**Note:** You must enclose multiple search patterns in braces {} to present the list as a single element.

**Examples**

The following example gets the interface ports in the subsystem design that operate in Master mode:

```
hsi::get_intf_ports -filter {MODE=="master"}
```

**Note:** If there are no interface ports matching the pattern, the tool will return a warning.

Software

Description

Get a list of libraries in the current software design.

Arguments

- regexp - (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ":,\" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

Note: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "."

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

"NAME", "VERSION", and "other config parameters" are some of the properties you can use to filter results for libraries. The following gets software libraries that which are named xilrsa and are version 1.0:

```
get_libs * -filter {NAME == xilrsa && VERSION == '1.0'}
```

-of_objects<arg> - (Optional) Get the subsystem cells that are connected to the specified pin or net objects as returned by the get_nets and get_pins, or by the get_intf_pins commands.

Note: The -of_objects option requires objects to be specified using one of the get_* commands such as get_cells or get_pins rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match subsystem cells against the specified patterns. The default pattern is the wildcard "*" which gets a list of all cells in the current IP subsystem design. More than one pattern can be specified to find multiple cells based on different search criteria.

Note: You must enclose multiple search patterns in braces {} to present the list as a single element.
Examples

The following example gets a list of libraries:

hsi::get_libs

See Also

- hsi::get_drivers
- hsi::get_os
- hsi::get_sw_processor
- common::report_property
hsi::get_mem_ranges

Get a list of memory ranges.

Syntax

```tcl
get_mem_ranges [-regexp] [-filter <arg>] [-hierarchical] [-of_objects <args>] [-quiet] [-verbose] [<patterns>...]
```

Returns

Memory range objects. Returns nothing if the command fails

Usage

<table>

Categories

Hardware

Description

Get a list of slaves of the processor in the current hardware design.

Arguments

- **-regexp**  - (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

  **Note:** The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

**Note:** The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "."

For string comparison, the specific operators that can be used in filter expressions are "equal" (==), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

-hierarchical - (Optional) Get memory ranges from all levels of hierarchical cells.

-of_objects<arg> - (Optional) Get the slaves of the specified object.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

**Note:** Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match address segments against the specified patterns. The default pattern is the wildcard `*` which gets a list of all address segments in the current IP subsystem design. More than one pattern can be specified to find multiple address segments based on different search criteria.

**Note:** You must enclose multiple search patterns in braces {} to present the list as a single element.

### Examples

The following example gets the slaves of the processor:

```tcl
hsi::get_mem_ranges
hsi::get_mem_ranges -of_objects [lindex [get_cells -filter [IP_TYPE==PROCESSOR] 0]
```
Note: If there are no objects matching the pattern you will get a warning.
hsi::get_nets

Get a list of nets.

Syntax

```
```

Returns

Net objects. Returns nothing if the command fails

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-regexp]</td>
<td>Patterns are full regular expressions</td>
</tr>
<tr>
<td>[-filter]</td>
<td>Filter list with expression</td>
</tr>

Hardware

Description

Gets a list of nets in the current hardware design that match a specified search pattern. The default command gets a list of all nets in the subsystem design.
Arguments

-\texttt{regexp} - (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -\texttt{filter} expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

\textbf{Note:} The Tcl built-in command \texttt{regexp} is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/reg.exp.htm.

-\texttt{filter}<\texttt{args}> - (Optional) Filter the results list with the specified expression. The -\texttt{filter} argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the \texttt{report_property} or \texttt{list_property} commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

\textbf{Note:} The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (\(!=\)), "match" (\(\sim\)), and "not-match" (\(\!\sim\)). Numeric comparison operators <, >, \(<=\), and \(\geq\) can also be used. Multiple filter expressions can be joined by AND and OR (\&\& and ||).

For the "hardware design " object you can use the "NAME" property to filter results.

-\texttt{boundary_type} - (Optional) Used when source object is on a hierarchical block's pin. Valid values are 'upper', 'lower', or 'both'. If 'lower' boundary, searches from the lower level of hierarchy onwards. This option is only valid for \texttt{connected_to} relations. Default: upper.

-\texttt{hierarchical} - (Optional) Get nets from all levels of hierarchical cells.

-\texttt{of_objects} - (Optional) Get 'net' objects of these types: 'hw_design cell port'.

-\texttt{quiet} - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

\textbf{Note:} Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-\texttt{verbose} - (Optional) Temporarily override any message limits and return all messages from this command.
Note: Message limits can be defined with the `set_msg_config` command.

<patterns> - (Optional) Match hardware design nets against the specified patterns. The default pattern is the wildcard `*` which returns a list of all nets in the current IP Integrator subsystem design. More than one pattern can be specified to find multiple nets based on different search criteria.

Note: You must enclose multiple search patterns in braces {} to present the list as a single element.

Examples

The following example gets the net attached to the specified pin of an hardware design module, and returns both the net:

```tcl
hsi::get_nets -of_objects [get_pins aclk]
```

Note: If there are no nets matching the pattern you will get a warning.

Categories

Software

Description

Get a list of nodes in drivers/os/nodes in the current software design.

A node can have child nodes in it.

Arguments

- **-regexp** (Optional) Specifies that the search `<patterns>` are written as regular expressions. Both search `<patterns>` and `-filter` expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.
**Note:** The Tcl built-in command `regexp` is not anchored, and works as a standard Tcl command. For more information refer to [http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm](http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm).

`-filter <args>` - (Optional) Filter the results list with the specified expression. The `-filter` argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the `report_property` or `list_property` commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard `*` character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

**Note:** The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the `*` wildcard character, this will match a property with a defined value of `""`.

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

The following gets nodes that matches NAME and PARENT within their name:

```
get_nodes -filter {NAME==clkc && PARENT == ps7_slcr_0}
```

`-of_objects <arg>` - (Optional) Get 'node' objects of these types: 'sw_driver', 'sw_os', 'sw_proc', 'sw_node'.

**Note:** The `-of_objects` option requires objects to be specified using the `get_*` commands, such as `get_nodes`, rather than specifying objects by name. In addition, `-of_objects` cannot be used with a search `<pattern>`

`-quiet` - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

`-verbose` - (Optional) Temporarily override any message limits and return all messages from this command.

**Note:** Message limits can be defined with the `set_msg_config` command.

`<patterns>` - (Optional) Match software design cells against the specified patterns. The default pattern is the wildcard `*` which gets a list of all cells in the current IP subsystem design. More than one pattern can be specified to find multiple cells based on different search criteria.

**Note:** You must enclose multiple search patterns in braces, {}, to present the list as a single element.
Examples

The following example gets a list of nodes that include the specified driver in the software design:

```tcl
hsi::get_nodes -of_objects [get_drivers ps7_uart_0]
```

The following example gets a list of all nodes of OS:

```tcl
hsi::get_nodes -of_objects [get_os]
```

See Also

- `hsi::get_comp_params`
- `hsi::get_drivers`
hsi::get_os

Get OS in the software design.

Syntax

```
[<patterns>...]
```

Returns

OS object. Returns nothing if the command fails

Hardware

Description

Gets a list of pin objects on the current hardware design that match a specified search pattern. The default command gets a list of all pins in the subsystem design.

Arguments

-regex (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.
Note: The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.

-filter <args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

Note: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

"DIR" and "TYPE" are some of the properties you can use to filter results for pins. The following gets input pins that do NOT contain the "RESET" substring within their name:

```
get_pins * -filter {DIRECTION == IN && NAME !~ "*RESET*"}
```

-hierarchical - (Optional) Get pins from all levels of hierarchical cells.

-of_objects <arg> - (Optional) Get the pins connected to the specified IP subsystem cell or net.

Note: The -of_objects option requires objects to be specified using one of the get_* commands such as get_cells or get_pins rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match hardware design pins against the specified patterns.
**Note:** More than one pattern can be specified to find multiple pins based on different search criteria. You must enclose multiple search patterns in braces {} to present the list as a single element.

### Examples

The following example gets a list of pins attached to the specified cell:

```tcl
hsi::get_pins -of [get_cells axi_gpio_0]
```

**Note:** If there are no pins matching the pattern, the tool will return a warning.

The following example gets a list of pins attached to the specified subsystem net:

```tcl
hsi::get_pins -of [get_nets ps7_axi_interconnect_0_M_AXI_BRESP]
```

### See Also

Hardware

Description

Gets a list of port objects in the current hardware design that match a specified search pattern. The default command gets a list of all ports in the hardware design.

The external connections in an hardware design are ports or interface ports. The external connections in an IP Integrator cell or hierarchical module are pins and interface pins. Use the `get_pins` and `get_intf_pins` commands to select the pin objects.
Arguments

- **regexp** - (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

**Note:** The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.

- **filter**<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

**Note:** The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (==), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and => can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For IP subsystem ports, "DIRECTION", "TYPE", and "SENSITIVITY" are some of the properties you can use to filter results.

- **of_objects**<arg> - (Optional) Get the ports connected to the specified IP subsystem nets returned by get_nets.

**Note:** The -of_objects option requires objects to be specified using one of the get_* commands such as get_cells or get_pins rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>

- **quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **verbose** - (Optional) Temporarily override any message limits and return all messages from this command.
Note: Message limits can be defined with the `set_msg_config` command.

<patterns> - (Optional) Match ports against the specified patterns. The default pattern is the wildcard `*` which gets a list of all ports in the subsystem design. More than one pattern can be specified to find multiple ports based on different search criteria.

Note: You must enclose multiple search patterns in braces {} to present the list as a single element.

Examples

The following example gets the ports connected to the specified hardware subsystem net:

```tcl
hsi::get_ports -of_objects [get_nets bridge_1_apb_m] -filter [DIRECTION==I]
```

Note: If there are no ports matching the pattern, the tool will return a warning.

Categories

Software

Description

Get a list of SW cores defined in the SW repository of the current session, based on the specified search pattern. The default is to return all SW cores defined in the repo.

Arguments

-regexp  (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

**Note:** The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (==), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

"NAME", "CORE_STATE", and "TYPE" are some of the properties you can use to filter results for sw_cores.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

**Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

**Note:** Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match IP core definitions in the IP catalog against the specified search patterns. The default pattern is the wildcard `*` which gets a list of all IP cores in the catalog. More than one pattern can be specified to find multiple core definitions based on different search criteria.

**Note:** You must enclose multiple search patterns in braces, {}, or quotes, "", to present the list as a single element.

**Examples**

The following example returns a list of all SW cores with TYPE property matching the specified pattern:

```
get_sw_cores -filter [TYPE == 'driver']
```
The following example returns a list of all SW cores with REPOSITORY property matching the specified pattern:

```
get_sw_cores -filter {REPOSITORY=="C:/user/repo"}
```
hsi::get_sw_designs

Get a list of software designs opened.

Syntax

```
get_sw_designs [-regexp] [-filter <arg>] [-quiet] [-verbose] [<patterns>...]
```

Returns

Software design objects. Returns nothing if the command fails

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-regexp</code></td>
<td>Patterns are full regular expressions</td>
</tr>
<tr>
<td><code>-filter</code></td>
<td>Filter list with expression</td>

<td>Ignore command errors</td>
</tr>
<tr>
<td><code>-verbose</code></td>
<td>Suspend message limits during command execution</td>
</tr>
<tr>
<td><code>&lt;patterns&gt;</code></td>
<td>Match design names against patterns Default: *</td>
</tr>
</tbody>
</table>

Categories

Software

Description

Gets a list of software designs open in the current HSM session that match a specified search pattern. The default command gets a list of all open software designs in the active session.

Arguments

- `-regexp` - (Optional) Specifies that the search `<patterns>` are written as regular expressions. Both search `<patterns>` and `-filter` expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add `".*"` to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

Note: The Tcl built-in command `regexp` is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "*" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

Note: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "*" wildcard character, this will match a property with a defined value of "".

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and => can also be used. Multiple filter expressions can be joined by AND and OR (&& and ||).

For software designs you can use "NAME" to filter results.

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match designs against the specified patterns. The default pattern is the wildcard "*" which gets all software designs. More than one pattern can be specified to find multiple designs based on different search criteria.

Examples

The following example gets all open Software designs in the current session:

```
get_sw_designs
```

Software

Description

Specifies the interfaces implemented by the library or driver and describes the interface functions and header files used by the library or driver.

Arguments

- **-regexp** - (Optional) Specifies that the search <patterns> are written as regular expressions. Both search <patterns> and -filter expressions must be written as regular expressions when this argument is used. Xilinx regular expression Tcl commands are always anchored to the start of the search string. You can add ".*" to the beginning or end of a search string to widen the search to include a substring. See http://www.tcl.tk/man/tcl8.5/TclCmd/re_syntax.htm for help with regular expression syntax.

**Note:** The Tcl built-in command regexp is not anchored, and works as a standard Tcl command. For more information refer to http://www.tcl.tk/man/tcl8.5/TclCmd/regexp.htm.
-filter<args> - (Optional) Filter the results list with the specified expression. The -filter argument filters the list of objects returned based on property values on the objects. You can find the properties on an object with the report_property or list_property commands.

You should quote the filter search pattern to avoid having to escape special characters that may be found in net, pin, or cell names, or other properties. String matching is case-sensitive and is always anchored to the start and to the end of the search string. The wildcard "**" character can be used at the beginning or at the end of a search string to widen the search to include a substring of the property value.

**Note**: The filter returns an object if a specified property exists on the object, and the specified pattern matches the property value on the object. In the case of the "**" wildcard character, this will match a property with a defined value of "."

For string comparison, the specific operators that can be used in filter expressions are "equal" (=), "not-equal" (!=), "match" (=~), and "not-match" (!~). Numeric comparison operators <, >, <=, and >= can also be used. Multiple filter expressions can be joined by AND and OR (&& and |). sw_interface, "NAME", and "other config parameters" are some of the properties you can use to filter results.

-of_objects<arg> - (Optional) Get the software interfaces that are available in OS, Drivers, Libraries, Processor, Core, as returned by the get_os, get_drivers, get_libs, get_sw_processor, get_sw_cores commands.

**Note**: The -of_objects option requires objects to be specified using one of the get_* commands such as get_os or get_libs rather than specifying objects by name. In addition, -of_objects cannot be used with a search <pattern>

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

**Note**: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

**Note**: Message limits can be defined with the set_msg_config command.

<patterns> - (Optional) Match software interfaces against the specified patterns. The default pattern is the wildcard `*` which gets a list of all software interfaces. More than one pattern can be specified to find multiple software interfaces based on different search criteria.

**Note**: You must enclose multiple search patterns in braces {} to present the list as a single element.
Examples

The following example gets a list of interfaces present in all software cores(drivers/libs/os)

```
get_sw_interfaces
```

The following example gets a list of all software interfaces matching the name "stdout"

```
get_sw_interfaces stdout
```

The following example gets a list of software interfaces present in OS of current software design.

```
get_sw_interfaces -of_objects [get_os]
```

See Also

Software

Description

Returns the processor object of the active software design or nothing if the command fails.

Arguments

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.
Examples

The following example returns the software processor of the current software design:

```
get_sw_processor
```

Hardware

Description

Opens a Hardware design in the Hardware Software Interface. The hardware design must be exported previously using the Vivado product. Users can open multiple hardware designs at the same time.

If successful, this command returns a hardware design object representing the opened Hardware design. Otherwise it returns an error.

Arguments

- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.
  
  **Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.
  
  **Note:** Message limits can be defined with the `set_msg_config` command.
<file> - The path and file name of the Hardware design to open in the HSM. The name must include the file extension.

**Examples**

Open the specified IP subsystem design in the current project:

```tcl
open_hw_design C:/Data/project1/project1.sdk/SDK/SDK_Export/hw/design_1.xml
```

OR

```tcl
open_hw_design C:/Data/project1/project1.sdk/design_1_wrapper.hdf
```

**See Also**

- `hsi::close_hw_design`
- `hsi::current_hw_design`
- `hsi::get_hw_designs`
hsi::open_sw_design

Open a software design from disk file.

Syntax

open_sw_design [-quiet] [-verbose] [<file>]

Returns

Software design object. Returns nothing if the command fails

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>

Software

Description

Open a software design in the Hardware Software Interface.

If successful, this command returns software design object representing the opened Software design. Otherwise it returns an error.

Arguments

-quiet - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.

Note: Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

-verbose - (Optional) Temporarily override any message limits and return all messages from this command.

Note: Message limits can be defined with the set_msg_config command.

<name> - The name of the software design to open.
Examples

Open the specified software design in the current session:

```tcl
open_sw_design sw_design_1
```

hsi::set_repo_path

Set a list of software repository paths.

Syntax

```tcl
set_repo_path [-quiet] [-verbose] <paths>..
```

Returns

Returns nothing

Usage

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-quiet]</td>
<td>Ignore command errors</td>
</tr>
<tr>
<td>[-verbose]</td>
<td>Suspend message limits during command execution</td>

Software

Description

Loads the software cores available in the repository path. Users can specify multiple repository paths.

Arguments

- **-quiet** - (Optional) Execute the command quietly, returning no messages from the command. The command also returns TCL_OK regardless of any errors encountered during execution.
  
  **Note:** Any errors encountered on the command-line, while launching the command, will be returned. Only errors occurring inside the command will be trapped.

- **-verbose** - (Optional) Temporarily override any message limits and return all messages from this command.
  
  **Note:** Message limits can be defined with the `set_msg_config` command.

- `<paths>` List of software repository paths separated by spaces.
Examples

The following example loads the user software cores in the current session:

```
set_repo_path C:/users/user_driver_repo
```
