Introduction

The Xilinx® LogiCORE™ IP Convolutional Encoder core can be used in a wide variety of error correcting applications and is typically used in conjunction with the Viterbi Decoder [Ref 3].

Features

- High-speed compact convolution encoder with puncturing option
- Parameterizable constraint length from three to nine
- Parameterizable convolution codes
- Parameterizable puncture codes
- Puncturing rates from 2/3 to 12/23 available

Overview

The Xilinx® Convolutional Encoder core is used to encode data prior to transmission over a channel. The received data is decoded by the classic Viterbi decoder. In a basic convolution encoder, two or three bits (depending on the encoder output rate) are transmitted over the channel for every input bit.

Applications

The core is used in a wide variety of error correcting applications and is typically used in conjunction with the Viterbi Decoder [Ref 3].

Unsupported Features

The core only supports a fixed rate puncturing option. The puncturing rate cannot be varied dynamically.

Licensing and Ordering

This Xilinx LogiCORE™ IP module is provided at no additional cost with the Xilinx Vivado® Design Suite under the terms of the Xilinx End User License.

Information about this and other Xilinx LogiCORE IP modules is available at the Xilinx Intellectual Property page. For information about pricing and availability of other Xilinx LogiCORE IP modules and tools, contact your local Xilinx sales representative.
Product Specification

The Convolutional Encoder core is used to encode data prior to transmission over a channel. The received data is decoded by the classic Viterbi decoder. In a basic convolution encoder, two or three bits (depending on the encoder output rate) are transmitted over the channel for every input bit.

The basic architecture of the Convolutional Encoder core is shown in Figure 2-1. The incoming data is brought into the constraint register a bit at a time, and the output bits are generated by modulo-2 addition of the required bits from the constraint register. The bits to be XOR'd are selected by the convolution codes as shown in Figure 2-1.

![Convolutional Encoder Constraint Length 9](image)

**Figure 2-1:** Convolutional Encoder Constraint Length 9

Standards

The Convolutional Encoder IP core uses the AXI4-Stream interface as per the AMBA® AXI4-Stream Protocol Specification (ARM IHI 0051A) [Ref 2].
Performance

This section details the performance information for various core configurations.

Latency

For this core, latency is defined as the number of rising clock edges from sampling S_DATA to the sampled value appearing on M_DATA. The latency varies with the puncture type and puncture rate. See Table 2-1 for some example latency figures.

Table 2-1: Latency

<table>

</tr>
<tr>
<td>Punctured non-dual rate 3/4</td>
<td>10</td>
</tr>
</tbody>
</table>

Throughput

The maximum raw data input rate in Mb/s can be calculated as $F_{\text{max}}(\text{MHz})$ for non-punctured and dual encoder and $F_{\text{max}}(\text{MHz}) \times n/m$ for the punctured non-dual encoder, where $n$ is the input rate and $m$ is the output rate of the punctured core.

Resource Utilization

For full details about performance and resource utilization, visit the Performance and Resource Utilization web page.

Resources required for the Convolutional Encoder core are of the order of a 20 to 100 LUTs depending on the selected puncture rate. The area of the core increases with the constraint length and the punctured input and output rates if the core is punctured.
Port Descriptions

Symbols for the core with the AXI channels are shown in Figure 2-2 and Figure 2-3.

Table 2-2 summarizes the signal functions. They are described in more detail in the remainder of this section. Timing diagrams for the signals are shown throughout this section.

</tbody>
</table>

Notes:
1. All AXI4-Stream port names are lower case, but for ease of visualization, upper case is used in this document when referring to port name suffixes, such as tdata or tlast.

**aclken**

The clock enable input (aclken) is an optional pin. When aclken is deasserted (Low), all the other synchronous inputs are ignored, except aresetn, and the core remains in its current state. This pin should be used only if it is genuinely required because it has a High fan out within the core and can result in lower performance. aclken is a true clock enable and causes the entire core to freeze state when it is Low.

An example of aclken operation is shown in Figure 2-4. In this case, the core ignores symbol D9 as input to the block, and the current m_axis_data_tdata value remains unchanged.
aresetn

The synchronous reset (aresetn) input can be used to re-initialize the core at any time, regardless of the state of aclken. aresetn needs to be asserted Low for at least two clock cycles to initialize the circuit. The core becomes ready for normal operation two cycles after aresetn goes High if aclken is High. The timing for the aresetn input is shown in Figure 2-5.

S_AXIS_DATA Channel

s_axis_data_tdata

Data to be processed is passed into the core on this port. To ease interoperability with byte-oriented buses, tdata is padded with zeros and for the convolutional encoder the bus is always 8 bits. The padding bits are ignored by the core and do not result in additional resource use. The structure is shown in Figure 2-6.
Chapter 2: Product Specification

**DATA_IN Field**

This is the input bit for the incoming data. The width of the DATA_IN field is always 1.

**s_axis_data_tlast**

This input can be tied Low or High if the event outputs (event_s_data_tlast_missing and event_s_data_tlast_unexpected) are not used. It is present purely to provide a check that the system and core are in sync with the applied puncturing. If the event outputs are used, then s_axis_data_tlast must be asserted High when the last symbol of a punctured group is sampled on s_axis_data_tdata. The core maintains its own internal count of the symbols, so it knows when the last symbol is being sampled. If s_axis_data_tlast is not sampled High when the last input symbol is sampled, then event_s_data_tlast_missing is asserted until the next input sample is taken. Similarly, if s_axis_data_tlast is sampled High when the core is not expecting it, event_s_data_tlast_unexpected is asserted until the next input sample is taken. If either of these events occurs, then the system and the core are out of sync and the core, and possibly the system, should be reset.

**Single-Channel Output**

For the single-channel output, after n input bits (puncture input rate) have been received, the tready signal goes Low for m-n (where m is the puncture output rate) clock periods. The m_axis_data_tvalid signal is used to indicate that valid output data is available which is output in a block of m bits (puncture output rate), as shown in Figure 2-9.

**Dual-Channel Output**

For the dual-channel punctured case, s_axis_data_tready is always High (unless aresetn has been asserted or back pressure has been applied). The dual channel puncturing works on two blocks of n bits of data. After 2n input bits have been received, where n is the punctured input rate, m symbols are output on m_axis_data_tdata (width 2) after a certain latency. The m_axis_data_tvalid signal indicates the valid outputs. The data is output in blocks of m symbols (width 2) and the m_axis_data_tvalid signal is High for m clock cycles and Low for the next 2n-m. See Figure 2-8 for the 3/4 rate dual-channel punctured encoder.
**M_AXIS_DATA Channel**

**m_axis_data_tdata**

Uncoded data sampled on s_axis_data_tdata is encoded and output from the core on this port. All output data is padded with zeros to fit a bit field which is always 8 bits. The structure is shown in Figure 2-7.

<table>
<thead>
<tr>
<th>Bit</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tdata</td>
<td>DATA OUT</td>
<td></td>
</tr>
</tbody>
</table>

*Figure 2-7: Output Data Channel TDATA Structure*

**DATA_OUT Field**

This is the output field for the encoded bits. The width depends on the type of encoder. For the case of unpunctured data, the width is equal to the output rate. For punctured data with serial output, the width is 1-bit and for the dual channel encoder the output width is 2 bits. Corrected symbols start to appear many clock cycles after the first symbol is sampled on DATA_IN.

**m_axis_data_tlast**

This output is High when the last DATA_OUT of a punctured block is on m_axis_data_tdata. The port is not present on the non-punctured core. In the dual output case, m_axis_data_tlast is only asserted High when m output pairs have been output, this corresponds to 2n data inputs (shown in Figure 2-8). For the serial case, the signal is asserted when m serial outputs have been output (shown in Figure 2-9).
Figure 2-8: Dual Output Timing for Rate 3/4 Puncturing

Figure 2-9: Serial Output Timing for Rate 3/4 Puncturing
This chapter includes guidelines and additional information to facilitate designing with the core.

### General Design Guidelines

#### Puncturing

The encoder can also puncture the data prior to transmission. In this case, the basic convolutional encoder is always a rate 1/2 encoder, two bits output for every one bit input. After the encoding, certain bits of the rate 1/2 encoded data are punctured (or deleted) and not transmitted. Thus, for a rate 3/4 punctured encoder, for every three input bits, only four of the six encoded bits generated by the encoder are actually transmitted, as shown in Figure 3-1. The two bits output from the encoder are punctured according to a pair of puncture codes. The puncture code is a bit pattern that identifies which bits from the encoder are to be transmitted. The use of puncturing significantly reduces the number of bits to be transmitted over the channel. For rate n/m puncturing, a puncture code of length n is used and exactly m bits are transmitted where n<m<2n. For rate n/m puncturing, the length of each puncture code must be n bits and the total number of non-zero bits must be equal to m.

**Note:** The order of application of the puncture code is now left to right and matches the order of application of the convolution codes, see Figure 3-1, puncture code 1. The value of n can range from 2 to 12.

![Figure 3-1: Punctured Encoding with Single-Channel Output](image-url)
Chapter 3: Designing with the Core

For the punctured encoder, the data can be output as a single bitstream, as shown in Figure 3-1. This single-channel output requires the use of the slave input \texttt{tvalid} and slave output \texttt{tready} as there are more bits output than bits input. Also, in the single-channel case, the \texttt{tready} signal is low for m-n clock cycles after receiving the n input bits, as shown Figure 2-8.

The data can also be output two bits at a time for the punctured encoder when the dual-channel output mode is selected, as shown in Figure 3-2. In this situation, there is less data output than input and the \texttt{tready} signal, if present, is only low if the master output data stream has been halted or the core reset. The master \texttt{tvalid} signal indicates when the output data is valid in both cases. For timing diagrams for the dual output case, see Figure 2-8.

![Figure 3-2: Puncture Encoding with Dual-Channel Output](X12356)

**Clocking**

The Convolutional Encoder core is a fully synchronous circuit with a single clock. All interfaces are synchronous to the rising edge of the \texttt{aclk} signal.

**Resets**

The core can be returned to its default state by driving the \texttt{aresetn} signal Low. On the cycle directly following the deassertion of \texttt{aresetn}, the core is again idle and ready to accept new data. An initial application of \texttt{aresetn} at startup is permitted, but is not strictly necessary.
Protocol Description

AXI4-Stream Protocol

The use of AXI4-Stream interfaces standardizes and enhances the interoperability of Xilinx® LogiCORE™ IP solutions. Other than general control signals such as aclk, aclken, aresetn, and event outputs, all inputs and outputs to the core are conveyed through AXI4-Stream channels. A channel consists of tvalid and tdata always, plus several optional ports and fields. In the Convolutional Encoder, the additional ports used are tready and tlast. Together, tvalid and tready perform a handshake to transfer a value, where the payload is tdata, and tlast. The payload is indeterminate when tvalid is deasserted.

The Convolutional Encoder operates on the values contained in the S_AXIS_DATA channel tdata fields and outputs the results in the tdata fields of the M_AXIS_DATA channel. The Convolutional Encoder core does not use input tlast as such, tlast is provided purely as a check that the core is in sync with the system and its use is optional. For further details on AXI4-Stream Interfaces see [Ref 1] and [Ref 2].

Basic Handshake

Figure 3-3 shows the transfer of data in an AXI4-Stream channel. tvalid is driven by the source (master) side of the channel and tready is driven by the receiver (slave). tvalid indicates that the value in the payload fields (tdata and tlast) is valid. tready indicates that the slave is ready to receive data. When both tvalid and tready are TRUE in a cycle, a transfer occurs. The master and slave set tvalid and tready, respectively for the next transfer appropriately.

The full flow control of AXI4-Stream aids system design because the flow of data is self-regulating. Data loss is prevented by the presence of back pressure (tready), so that data is only propagated when the downstream datapath is ready to process it.

The core has one output channel: M_AXIS_DATA. If the output is prevented from off-loading data because m_axis_data_tready is low then data accumulates in the core.
core internal buffers are full the core stops further operations. When the internal buffers fill, the `tready (s_axis_data_tready)` is deasserted to prevent further input. This is the normal action of back pressure.

**Note:** The convolutional encoder is designed for continuous data. In the situation where input data is packetized, the end of a packet will result in incomplete output because each output bit of a channel is a function of multiple input bits of that channel. The core cannot differentiate between the end of a packet and a simple pause in input, so it will cease processing pending new input. As a result, in this situation, to force out the final few bits of output for a packet, input padding bits with a value of 0 must be input until all required output bits have been output.
Design Flow Steps

This chapter describes customizing and generating the core, constraining the core, and the simulation, synthesis and implementation steps that are specific to this IP core. More detailed information about the standard Vivado® design flows and the IP integrator can be found in the following Vivado Design Suite user guides:

- *Vivado Design Suite User Guide: Designing with IP* (UG896) [Ref 5]

Customizing and Generating the Core

This section includes information about using Xilinx® tools to customize and generate the core in the Vivado® Design Suite.

If you are customizing and generating the core in the Vivado IP Integrator, see the *Vivado Design Suite User Guide: Designing IP Subsystems using IP Integrator* (UG994) [Ref 4] for detailed information. IP Integrator might auto-compute certain configuration values when validating or generating the design. To check whether the values do change, see the description of the parameter in this chapter. To view the parameter value you can run the `validate_bd_design` command in the Tcl console.

You can customize the IP for use in your design by specifying values for the various parameters associated with the IP core using the following steps:

1. Select the IP from the IP catalog.
2. Double-click the selected IP or select the Customize IP command from the toolbar or right-click menu.

For details, see the *Vivado Design Suite User Guide: Designing with IP* (UG896) [Ref 5] and the *Vivado Design Suite User Guide: Getting Started* (UG910) [Ref 6].
The customization parameters on the Vivado Integrated Design Environment (IDE) for the Convolutional Encoder are as follows.

**Component Name**

The component name is used as the base name of the output files generated for the core. Names must begin with a letter and must be composed from the following characters: a to z, 0 to 9 and "_".

**Data Rates and Puncturing**

**Punctured**

This parameter determines whether the core is punctured.

- **Not Punctured**: Only the output rate can be modified. Its value can be integer values from 2 to 7, resulting in a rate 1/2 to rate 1/7 encoder.
- **Punctured**: Both the input rate and output rate can be modified. The input value can range from 2 to 12, resulting in a rate n/m encoder where n is the input rate and n < m < 2n.

**Punctured Codes**

The two puncture pattern codes used to remove bits from the encoded data prior to output. The length of each puncture code must be equal to the puncture input rate, and the total number of bits set to 1 in the two codes must equal the puncture output rate (m) for the codes to be valid. A 0 in any position indicates that the output bit from the encoder is not transmitted. See Figure 3-1 for an example of a rate 3/4 punctured encoder. For the puncturing case, the data can be output in a single bitstream or in the dual-channel mode where the data is output in parallel two bits at a time.

**Convolution**

**Constraint Length**

The length of the constraint register plus 1 in the encoder. This value can be in the range 3 to 9, inclusive.

**Convolution Codes**

Convolution codes are used to generate the encoder outputs. For a punctured core, only two are required, because the encoder internal to the punctured core is always rate 1/2. The codes can be entered in binary, octal or decimal and have length equal to the constraint length.
**Optional Pins**

Check the boxes of the optional pins that are required. Select only pins that are genuinely required, as each selected pin uses more FPGA resources and can result in a less-than-maximum operating frequency.

**User Parameters**

*Table 4-1* shows the relationship between the fields in the Vivado IDE and the User Parameters (which can be viewed in the Tcl Console).

**Output Generation**

For details, see the *Vivado Design Suite User Guide: Designing with IP* (UG896) [Ref 5].
System Generator for DSP

The Convolutional Encoder core is also available through Xilinx System Generator for DSP, a design tool that enables the use of the Simulink® model-based design environment for FPGA design. The Convolutional Encoder core is one of the DSP building blocks provided in the Xilinx blockset for Simulink. The core can be found in the Xilinx Blockset in the Communication section. The block is called “Convolutional Encoder 9.0.” See the System Generator for DSP User Guide (UG640) [Ref 11] for more information.

The controls in the System Generator GUI work identically to those in the Vivado Design Suite IDE, although the layout differs.

Constraining the Core

This section contains information about constraining the core in the Vivado Design Suite.

Required Constraints

This section is not applicable for this IP core.

This section is not applicable for this IP core.

Simulation
For comprehensive information about Vivado simulation components, as well as information about using supported third party tools, see the Vivado Design Suite User Guide: Logic Simulation (UG900) [Ref 7].

Synthesis and Implementation
For details about synthesis and implementation, see the Vivado Design Suite User Guide: Designing with IP (UG896) [Ref 5].
Test Bench

This chapter contains information about the test bench provided in the Vivado® Design Suite.

Demonstration Test Bench

When the core is generated using the Vivado Design Suite, a demonstration test bench is created. This is a simple VHDL test bench that exercises the core.

The demonstration test bench source code is one VHDL file: `<component_name>/demo_tb/tb_<component_name>.vhd` in the Vivado IP catalog output directory. The source code is comprehensively commented.

Using the Demonstration Test Bench

The general steps for using the demonstration test bench are:

1. Compile the netlist and the demonstration test bench into the work library. See your simulator documentation for detailed information.
2. Simulate the demonstration test bench.
3. View the test bench signals in your simulator waveform viewer to see the operations of the test bench.

Demonstration Test Bench in Detail

The demonstration test bench performs the following tasks:

- Instantiates the core
- Generates a clock signal
- Drives the core input signals to demonstrate core features
- Checks that the core output signals follow AXI protocol rules (data values are not checked to keep the test bench simple)
- Provide signals showing the separate fields of AXI `tdata` signals
The demonstration test bench drives the core input signals to demonstrate the features and modes of operation of the core. The operations performed by the demonstration test bench are appropriate for the configuration of the generated core and are a subset of the following operations:

1. An initial phase where the core is initialized and no operations are performed.
2. Drive random data into the core to demonstrate convolutional encoding.
3. Demonstrate the use of AXI handshaking signals tvalid and tready.
4. Demonstrate the effect of asserting aresetn.
5. If aclken is present: demonstrate the effect of toggling aclken.

**Customizing the Demonstration Test Bench**

It is possible to modify the demonstration test bench to use different source data. Source data is generated randomly and driven into the core by the procedures of the s_data_stimuli process. The clock frequency of the core can be modified by changing the CLOCK_PERIOD constant.
Appendix A

Upgrading

This appendix contains information about migrating a design from ISE® to the Vivado® Design Suite, and for upgrading to a more recent version of the IP core. For customers upgrading in the Vivado Design Suite, important details (where applicable) about any port changes and other impact to user logic are included.

Migrating to the Vivado Design Suite

For information about migrating to the Vivado Design Suite, see the ISE to Vivado Design Suite Migration Guide (UG911) [Ref 8].

Parameter Changes

The Vivado Design Suite IP update feature can be used to update an existing XCO file from v7.0 and v8.0 to v9.0, but the update mechanism alone does not create a core compatible with v7.1. Table A-1 shows the changes to XCI parameters from v7.0 and v8.0 to v9.0.

Table A-1: Parameter Changes from v7.0 to v8.0 and 9.0

Upgrading in the Vivado Design Suite

This section provides information about any changes to the user logic or port designations that take place when you upgrade to a more current version of this IP core in the Vivado Design Suite.

**Parameter Changes**

No changes.

**Port Changes**

No changes.

**Other Changes**

No changes.
Debugging

This appendix includes details about resources available on the Xilinx Support website and debugging tools.

Finding Help on Xilinx.com

To help in the design and debug process when using the Convolutional Encoder core, the Xilinx Support web page contains key resources such as product documentation, release notes, answer records, information about known issues, and links for obtaining further product support.

Documentation

This product guide is the main document associated with the Convolutional Encoder. This guide, along with documentation related to all products that aid in the design process, can be found on the Xilinx Support web page or by using the Xilinx® Documentation Navigator.

Download the Xilinx Documentation Navigator from the Downloads page. For more information about this tool and the features available, open the online help after installation.

Answer Records

Answer Records include information about commonly encountered problems, helpful information on how to resolve these problems, and any known issues with a Xilinx product. Answer Records are created and maintained daily ensuring that users have access to the most accurate information available.

Answer Records for this core can be located by using the Search Support box on the main Xilinx support web page. To maximize your search results, use keywords such as:

- Product name
- Tool messages
- Summary of the issue encountered

A filter search is available after results are returned to further target the results.
Master Answer Record for the Convolutional Encoder

AR: 54496

Technical Support

Xilinx provides technical support in the Xilinx Support web page for this LogiCORE™ IP product when used as described in the product documentation. Xilinx cannot guarantee timing, functionality, or support if you do any of the following:

- Implement the solution in devices that are not defined in the documentation.
- Customize the solution beyond that allowed in the product documentation.
- Change any section of the design labeled DO NOT MODIFY.

To contact Xilinx Technical Support, navigate to the Xilinx Support web page.

Debug Tools

There are debug tools available to address Convolutional Encoder design issues.

Vivado Design Suite Debug Feature

The Vivado® Design Suite debug feature inserts logic analyzer and virtual I/O cores directly into your design. The debug feature also allows you to set trigger conditions to capture application and integrated block port signals in hardware. Captured signals can then be analyzed. This feature in the Vivado IDE is used for logic debugging and validation of a design running in Xilinx devices.

The Vivado logic analyzer is used with the logic debug IP cores, including:

- ILA 2.0 (and later versions)
- VIO 2.0 (and later versions)

See the Vivado Design Suite User Guide: Programming and Debugging (UG908) [Ref 10].

Hardware Debug

Hardware issues can range from link bring-up to problems seen after hours of testing. This section provides debug steps for common issues. The Vivado debug feature is a valuable resource to use in hardware debug. The signal names mentioned in the following individual sections can be probed using the debug feature for debugging the specific problems.
Appendix B: Debugging

General Checks

Ensure that all the timing constraints for the core were properly incorporated from the example design and that all constraints were met during implementation.

- Does it work in post-place and route timing simulation? If problems are seen in hardware but not in timing simulation, this could indicate a PCB issue. Ensure that all clock sources are active and clean.
- If using MMCMs in the design, ensure that all MMCMs have obtained lock by monitoring the locked port.
- If your outputs go to 0, check your licensing.

AXI4-Stream Interface Debug

If data is not being transmitted or received, check the following conditions:

- If the transmit s_axis_data is stuck Low, the core cannot send data.
- If the receive m_axis_data is stuck Low, the core is not receiving data.
- Check that the aclk inputs are connected and toggling.
- Check that the AXI4-Stream waveforms are being followed Figure 3-3.
- Check core configuration.
Appendix C

Additional Resources and Legal Notices

Xilinx Resources
For support resources such as Answers, Documentation, Downloads, and Forums, see Xilinx Support.

Documentation Navigator and Design Hubs
Xilinx® Documentation Navigator provides access to Xilinx documents, videos, and support resources, which you can filter and search to find information. To open the Xilinx Documentation Navigator (DocNav):

- From the Vivado® IDE, select Help > Documentation and Tutorials.
- On Windows, select Start > All Programs > Xilinx Design Tools > DocNav.
- At the Linux command prompt, enter docnav.

Xilinx Design Hubs provide links to documentation organized by design tasks and other topics, which you can use to learn key concepts and address frequently asked questions. To access the Design Hubs:

- In the Xilinx Documentation Navigator, click the Design Hubs View tab.
- On the Xilinx website, see the Design Hubs page.

Note: For more information on Documentation Navigator, see the Documentation Navigator page on the Xilinx website.
